## 760. The Dissociation Pressure of Cadmium Oxide.

By I. G. F. Gilbert and J. A. Kitchener.

The partial pressure of cadmium over solid cadmium oxide has been determined between $880^{\circ}$ and $1100^{\circ} \mathrm{c}$ by an accurate form of the entrainment method. The influence of increased oxygen pressure, and comparison with thermodynamic calculations, establish that the vapour is almost completely dissociated. The standard Gibbs free energy of the dissociation $\mathrm{CdO}(\mathrm{s})=\mathrm{Cd}(\mathrm{g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g})$ is found to be

$$
\Delta G^{\circ}\left(\text { at } 1150 — 1374^{\circ} \mathrm{K}\right)\left( \pm 150^{\circ}\right)=86,120( \pm 2900)-48.84( \pm 2.5) T\left(\text { cal. mole }{ }^{-1}\right)
$$

BRewer and Mastick ${ }^{1}$ have recently concluded from examination of earlier, approximate, data for the sublimation pressure of cadmium oxide that the vapour of this substance, like those of mercury(I), zinc, ${ }^{2}$ and lead(II) oxides, is probably almost completely dissociated. The partial pressures of cadmium (free or combined) in equilibrium with solid cadmium oxide in presence of nitrogen and in pure oxygen have now been determined by an accurate form of the entrainment method.

## Experimental

Method.-The reaction vessel is shown in Fig. I, and is a development of that used by Kitchener and Ignatowicz, ${ }^{4}$ the inlet tube being sealed directly in the hot zone to the tube

Fig. 1.

Fig. 2.

containing the cadmium oxide. The oxide (Hopkin and Williams) was previously sintered at $c a$. $1000^{\circ}$. Temperature was measured to $\pm 1^{\circ}$ by a platinum/platinum-rhodium thermocouple, and maintained within $\pm 1^{\circ}$ by an energy-regulator.

Nitrogen from a cylinder (" oxygen-free"; $<0.001 \%$ of oxygen) and oxygen, also from a cylinder, used as the entraining gases, were dried with anhydrous magnesium perchlorate.

[^0]Gas volumes were measured with a Hyde-pattern wet-test meter, calibrated to $\pm 0.2 \%$ under closely similar conditions.

The quantity of cadmium carried over into the condenser was determined by slow electrodeposition from weakly alkaline cyanide solution; the method was reliable to $\pm 0.8 \%$ for the small quantities collected in these experiments.

Procedure.-After the furnace had attained a steady temperature, the condenser was inserted and sealed in place with picein wax. Gas was passed through the bed of oxide (but not through the condenser) to remove air. In the actual determination, only part of the gas stream flowed through the condenser, its volume being measured by the gas-meter. This procedure was to eliminate back-diffusion. At the end of the run, the condenser was quickly removed from the furnace. The deposited cadmium was dissolved in dilute hydrochloric acid, and chloride (which interferes with the analysis) removed by evaporation with dilute nitric acid.

The quantity of cadmium diffusing into the condenser during the preparatory period was found to be negligible.

Results.-The partial pressure of cadmium ( $p_{\mathrm{Cd}}$, in $\mathrm{mm} . \mathrm{Hg}$,) was calculated by the ideal-gas laws, with use of the formula

$$
p_{\mathrm{Cd}}=\frac{(P+p)}{1+(112 \cdot 4 / \boldsymbol{R})\left[V\left(P-p_{\mathrm{w}}\right) / T w\right]}
$$

where $P$ (mm.) is the atmospheric pressure, $p$ ( mm .) is the (small) excess of pressure in the furnace, $T\left({ }^{\circ} \mathrm{K}\right)$ the temperature of the gas meter, $p_{\mathrm{w}}(\mathrm{mm}$.) the parial pressure of water vapour at $T^{\circ} \mathrm{K}, V(\mathrm{l}$.$) the volume of permanent gas collected, and w(\mathrm{~g}$.$) the weight of cadmium deposited.$

| Temp. (c) | Press. of Cd (mm.) | Total gas flow rate (c.c./min.) | Temp. (c) | Press. of Cd (mm.) | Total gas flow rate (c.c./min.) | Temp. (c) | Press. of Cd (mm.) | Total gas flow rate (c.c./min.) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Carrier gas : nitrogen |  |  |  |  |  |  |  |  |
| $880^{\circ}$ | $0 \cdot 132$ | 88 | $958{ }^{\circ}$ | $0 \cdot 630$ | 30 | $1009^{\circ}$ | 1.72 | 220 |
| 890 | $0 \cdot 179$ | 120 | 963 | 0.740 | 30 | 1010 | $1 \cdot 69$ | 110 |
| 903 | $0 \cdot 218$ | 66 | 966 | $0 \cdot 865$ | 40 | 1051 | $3 \cdot 33$ | 150 |
| 927 | $0 \cdot 345$ | 125 | 968 | 0.939 | 50 | 1053 | $3 \cdot 51$ | 78 |
| 928 | $0 \cdot 328$ | 88 | 1001 | $1 \cdot 42$ | 76 | 1053 | $3 \cdot 51$ | 200 |
| 934 | $0 \cdot 375$ | 50 | 1006 | $1 \cdot 65$ | 140 | 1101 | $7 \cdot 36$ | 100 |
| Carrier gas : oxygen |  |  |  |  |  |  |  |  |
| 925 | 0.005 | - | 983 | 0.015 | - |  |  |  |

Results.-These are shown in the Table. There is seen to be no systematic variation of $P_{C d}$ with flow-rate, indicating that a true equilibrium had been reached and measured.

Fig. 2 shows that, with an inert entraining gas, $\log p_{\mathrm{Cd}}$ is linear with $1 / T$ over the range $880-1100^{\circ} \mathrm{c}$ within experimental error. The least-squares line is given by :

$$
\begin{equation*}
\log _{10} p_{\mathrm{Cd}}(\mathrm{~mm} .)=10.008-12,548 / T \tag{1}
\end{equation*}
$$

The standard deviation of the points from the line is $\pm 0.029$.

## Discussion

The results obtained with oxygen as the entraining gas are smaller by a factor of about 80 than those with nitrogen, demonstrating that oxygen takes part in the equilibrium studied, and that the proportion of molecular cadmium oxide in the vapour above the oxide in nitrogen is certainly very small. In fact, the observed quantities of cadmium obtained with oxygen accord, within the experimental error, with the assumption of complete dissociation.

On this basis, the equilibrium constant ( $K=p_{\mathrm{Cd}} \cdot p_{\mathrm{O}_{2}}$ ) for the decomposition

$$
\mathrm{CdO}(\mathrm{~s})=\mathrm{Cd}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g})
$$

follows from equation (1), as

$$
\begin{equation*}
\log _{10} K\left(\mathrm{~atm} .^{3 / 2}\right)=10 \cdot 691-18 \cdot 822 / T \tag{2}
\end{equation*}
$$

and hence the standard Gibbs free energy of the reaction, $\Delta G^{\circ}$, is given by :

$$
\Delta G^{\circ}\left(\text { at } 1150-1374^{\circ} \text { к }\right)\left( \pm 150^{\circ}\right)=86,120( \pm 2900)-48 \cdot 84( \pm 2 \cdot 5) T\left(\text { cal. mole }{ }^{-1}\right)
$$

To confirm the conclusion that vaporization occurs only through dissociation, these results have been compared with thermodynamic calculations based on a calorimetric value of the heat of formation of $\mathrm{CdO}(\mathrm{s}),{ }^{5}$ vapour-pressure data for cadmium metal, and heat content and entropy data (see Appendix). The resulting equation for $\log p_{\mathrm{Cd}}$ was found to be (perhaps fortuitously) indistinguishable from experimental results shown in Fig. 2.

These thermodynamic data are not affected by the non-stoicheiometry of cadmium oxide which is negligible in extent under the conditions studied; even with 1 atm. of cadmium vapour, the excess of metal amounts to only $0 \cdot 5 \%{ }^{.}{ }^{6}$

We thank Mr. J. Lumsden for helpful discussions, Dr. Azzam for preliminary experimental work, and the Imperial Smelting Corporation for a bursary (I. G. F. G.).

## Appendix

Calculation, from thermodynamic data, of the free energy of the reaction:

$$
\begin{equation*}
\mathrm{CdO}(\mathrm{~s})=\mathrm{Cd}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \tag{i}
\end{equation*}
$$

The standard heat of the above reaction at $25^{\circ} \mathrm{C}\left(298 \cdot 1^{\circ} \mathrm{K}\right), \Delta H^{\circ}{ }_{298}$, is obtained from Mah's value ${ }^{5}$ for the reaction :

$$
\mathrm{Cd}(\mathrm{~s})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g})=\mathrm{CdO}(\mathrm{~s}), \text { namely, } \Delta H_{298}=-61,200( \pm 200) \mathrm{cal} .
$$

together with a value for the heat of sublimation, $\Delta H_{\text {sub. }}$ calculated from Egerton and Raleigh's vapour-pressure data. ${ }^{7}$ Their results lead to $\Delta H_{\text {sub. }}$ at $500^{\circ} \mathrm{K}=\mathbf{2 6 , 5 9 0}$. The specific heats of $\mathrm{Cd}(\mathrm{g})$ and $\mathrm{Cd}(\mathrm{s})$ are 4.97 and $\left(5.31+2.94 \times 10^{-3} T\right)$ respectively. ${ }^{8} \quad$ Hence, by Kirchhoff's equation, $\Delta H_{\text {sub. }}$ at $298^{\circ} \mathrm{K}$ is obtained as $+26,900 \mathrm{cal}$, giving, for reaction (i)

$$
\Delta H^{\circ}{ }_{298}=+88,100 \mathrm{cal}
$$

The standard entropy of the reaction is obtained from the following absolute entropies at $298.1^{\circ} \mathrm{K}$ : for $\mathrm{Cd}(\mathrm{g}), 40.07 \pm 0.01$ (Sackur's equation); for CdO (s), $13.1 \pm 0.3$ from Millar's low-temperature specific-heat determinations; ${ }^{9}$ for $\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}), 24 \cdot 31 \pm 0 \cdot 01$ (Kelley ${ }^{8}$ ). Hence, for reaction (i)

$$
\text { and } \begin{aligned}
\Delta S^{\circ}{ }_{298} & =+51 \cdot 45 \pm 0 \cdot 3 \text { cal. degree }{ }^{-1} \\
\Delta G^{\circ}{ }_{298} & =+72,800 \mathrm{cal} .
\end{aligned}
$$

To obtain a free-energy equation for a range of temperatures, use is made of the following specific heats: for $\mathrm{CdO}(\mathrm{s}), C_{p}=9.78+2.02 \times 10^{-3} T$ (estimated by Kelley ${ }^{8}$ ); for $\frac{1}{2} \mathrm{O}_{2}$, $C_{\mathrm{p}}=3.58+0.50 \times 10^{-3} T-0.20 \times 10^{5} T^{-2}$ (Kelley ${ }^{8}$ ); for $\mathrm{Cd}(\mathrm{g}), C_{\mathrm{p}}=4.97$ (monatomic gas).

By standard methods, the final equation is obtained as

$$
\Delta G_{\mathrm{T}}{ }^{\circ}=88,465+1.23 T \ln T+7.6 \times 10^{-4} T^{2}+1.0 \times 10^{4} T^{-1}-59.84 T
$$

The uncertainty in this equation probably does not exceed 1 kcal . at $1000^{\circ} \mathrm{\kappa}$.
