# 512. Molecular Polarisability. The Anisotropies of the Molecules $\mathrm{PCl}_{3}, \mathrm{OPCl}_{3}, \mathrm{NMe}_{3}$, and $\mathrm{ONMe}_{3}$. 

By N. Hacket and R. J. W. Le Fèvre.

The increase of molecular refractivity from trimethylamine to the oxide and the decrease from phosphorus trichloride to oxychloride have been investigated by determining the principal polarisabilities of these molecules. The polarisability of trimethylamine becomes greater, both along and across the direction of action of the resultant molecular dipole moment, when the oxide is formed. With phosphorus trichloride, addition of an oxygen atom notably reduces the polarisability across $\mu_{\text {resultant }}$. Attempts to calculate principal polarisabilities by using empirical equations involving bond lengths, stretching frequencies, etc., are reasonably satisfactory in three cases, but for phosphorus oxychloride, $b_{1}$ emerges $c a .20 \%$ too large, although a contraction in $b_{2}=b_{3}$ from phosphorus trichloride is qualitatively predicted.

Molar Kerr constants at infinite dilution, $\infty\left({ }_{m} K_{2}\right)$, are here recorded at $25^{\circ}$ for phosphorus trichloride and oxychloride in benzene and for trimethylamine oxide in dioxan. From the observed dipole moments, molecular refractions, etc., and with an assumption that these molecules have rotational symmetry about the direction of action of $\mu_{\text {resultant }}$, estimates of the principal polarisabilities follow, as in Table 1.

Table 1. Molar Kerr constants, moments, and principal polarisabilities.

| Solute | Solvent | $10^{12} \infty\left({ }_{m} K_{2}\right)$ | $\mu, \mathrm{D}^{*}$ | $10^{23}\left(b_{1}+2 b_{2}\right)$ | $10^{23} b_{1}$ | $10^{23}\left(b_{2}=b_{3}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{PCl}_{3}$ | Benzene | $-10.92$ | $0 \cdot 89{ }_{0}$ | 3.012 | 0.914 | 1.049 |
| $\mathrm{OPCl}_{3}$ |  | $-73 \cdot 8$ | $2 \cdot 42{ }^{3}$ | 2.936 | 0.902 | 1.017 |
| $\mathrm{ONMe}_{3}$ | Dioxan | $210 \cdot 0$ | $5 \cdot 03$ | 2.505 | 0.885 | $0 \cdot 810$ |

Discussion.-None of these three compounds has previously been examined in this way, nor does the literature indicate the degrees of anisotropy to be expected for the bonds between phosphorus and chlorine or oxygen, or between nitrogen and oxygen. It has, however, been noted ${ }^{1}$ with phosphorus trichloride and oxychloride that the smaller molecule has the larger molecular refraction, i.e. that the addition of an oxygen atom to the trichloride reduces the average polarisability. The results in Table l suggest that the diminution occurs more in $b_{2}$ than in $b_{1}$. Unfortunately, owing to the smallness of $\mu_{\text {resultant }}$ for phosphorus trichloride, its precise value is much affected by the distortion polarisation, ${ }_{\mathrm{D}} P$, used in its extraction from the ${ }_{\infty} P_{2}$ observed. A moment of 0.89 D is given when ${ }_{\mathrm{D}} P=$ $1.05 R_{\mathrm{D}}=27.6$ c.c. Grassi, ${ }^{2}$ from a study of the total polarisation of phosphorus trichloride as a vapour, records the temperature-invariant term in the Debye equation $P=A+B / T$ as 32.2 c.c.; taking 32.2 c.c. as ${ }_{\mathrm{D}} P$ yields $\mu_{\mathrm{PCl}_{3}}=0.75_{3} \mathrm{D}$, and in consequence $10^{23} b_{1}=0.858$ and $10^{23}\left(b_{2}=b_{3}\right)=1.077$. Nevertheless, although $b_{1}$ for $\mathrm{OPCl}_{3}$ now appears larger than that for $\mathrm{PCl}_{3}$, we see that diminution of $b_{2}$ from $\mathrm{PCl}_{3}$ to $\mathrm{OPCl}_{3}$ is still the preponderant change, and evidently that which makes $R_{\mathrm{PCl}_{3}}$ greater than $R_{\mathrm{OPCl}_{3}}$.

The cases of trimethylamine and its oxide differ from those of the phosphorus halides. Aroney and Le Fèvre ${ }^{3}$ found for trimethylamine $10{ }^{23} b_{1}=0.774$ and $10^{23}\left(b_{2}=b_{3}\right)=$ 0.763 ; addition of oxygen therefore increases both $b_{1}$ and $b_{2}$, the former ( $\Delta b_{1}=0.111$ ) more than the latter ( $\Delta b_{2}=0.047$ ), consistently with $R_{\text {ONMes }_{3}}$ exceeding $R_{\text {NMe }_{3}}$.

The causes of these changes in polarisability seem unlikely to be entirely structural in origin because the $\mathrm{Y}-\mathrm{X}$ bonds in the $\mathrm{YX}_{3}$ portions of the two oxygenated molecules are,
${ }^{1}$ Ingold, " Structure and Mechanism in Organic Chemistry," Cornell University Press, New York, 1953.
${ }^{2}$ Grassi, Nuovo Cimento, 1933, 10, 3.
${ }^{3}$ Aroney and Le Fèvre, J., 19583002.
if anything, slightly more splayed than when in the free $\mathrm{YX}_{3}$ molecules, a circumstance which-provided $b_{\mathrm{L}}^{\mathrm{P}-\mathrm{Cl}}>b_{\mathrm{T}}^{\mathrm{P}-\mathrm{Cl}}=b_{\mathrm{V}}^{\mathrm{P}-\mathrm{Cl}}$-should tend to make $b_{2}$ for $\mathrm{OPCl}_{3}$ larger than $b_{2}$ for $\mathrm{PCl}_{3}$. More probably the process of attaching an oxygen atom in fact changes the polarisabilities of the $\mathrm{C}-\mathrm{N}$ and $\mathrm{Cl}-\mathrm{P}$ links in opposite ways. We note that from $\mathrm{NMe}_{3}$ to $\mathrm{ONMe}_{3}$ the intercentre distance ${ }^{4} r_{\mathrm{N}-\mathrm{O}}$ increases by $0 \cdot 12 \AA$, while from $\mathrm{PCl}_{3}$ to $\mathrm{OPCl}_{3} r_{\mathrm{P}-\mathrm{Cl}}$ diminishes from 2.04 to $1.99 \AA$. These facts can be reconciled by the arguments of Walsh ${ }^{5}$ according to which bond length and bond polarity vary together. The establishment of the strongly ${ }^{6}$ polar NO and PO bonds will, by induction, augment the component moments of the $\mathrm{C} \rightarrow \mathrm{N}$ bonds and reduce those of the $\mathrm{Cl} \leftarrow \mathrm{P}$ bonds; the alterations of $r_{\mathrm{XY}}$ from $\mathrm{YX}_{3}$ to $\mathrm{OYX}_{3}$ are therefore understandable.

Longitudinal bond polarisabilities and bond lengths. Two ${ }^{7}$ empirical connections (equations $A$ and $B$ ) between these properties have been suggested:

$$
\begin{equation*}
10^{24} b_{\mathrm{L}}^{\mathrm{X}-\mathrm{Y}}=0 \cdot 140+0 \cdot 156 d^{3} \tag{A}
\end{equation*}
$$

where $d$ is the intercentre distance $r_{\mathrm{XY}}$, or if Y is a terminal atom, the sum of $r_{\mathrm{XY}}$ and the radius of $Y, r_{Y}$ (i.e. 0.995 for chlorine), and

$$
\begin{equation*}
v_{\mathrm{XY}}=9273 Q-254 \tag{B}
\end{equation*}
$$

where $Q=\left(b_{\mathrm{L}}^{\mathrm{X}}-\mathrm{Y} / \mathrm{M}\right)^{\frac{1}{d}} / \boldsymbol{r}^{2}{ }_{\mathrm{XY}} ; v_{\mathrm{XY}}$ being the stretching frequency of the bond $\mathrm{X}-\mathrm{Y}$ in $\mathrm{cm} .^{-1}$, and $M$ is the reduced mass of $X-Y$.

In the present instances, data taken as in Table 2 lead to the values of $b_{\mathrm{L}}^{\mathrm{XY}}$ shown. The
Table 2. Calculation of longitudinal polarisabilities by equations $A$ and $B$.

| Molecule | XY | $r_{\text {XY }}(\AA)$ | $\nu_{\mathrm{XXY}}\left(\mathrm{cm} .^{-1}\right)$ | $10^{23} b_{\mathrm{L}}$ <br> (from eqn. A) | $10^{23} b_{L}$ <br> (from eqn. B) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{PCl}_{3}$ | $\mathrm{P}-\mathrm{Cl}$ | 2.043 | 488 | 0.451 | $0.61{ }_{\text {g }}$ |
| $\mathrm{OPCl}_{3}$ | $\mathrm{P}-\mathrm{Cl}$ | 1.99 | 485 | $0 \cdot 429$ | 0.52 \% |
|  | PO | $1 \cdot 45$ | 1290 | ? | $0 \cdot 45$ |

| $\mathrm{ONMe}_{3}$ | $\mathrm{C}-\mathrm{N}$ | 1.59 | ? | $0 \cdot 063$ | ? |
| ,, | NO | 1.36 | 960 | ? | $0 \cdot 10{ }_{6}$ |

values of $r_{\mathrm{XY}}$ are as listed in ref. 4. The two $\mathrm{P}-\mathrm{Cl}$ frequencies are given by Daasch and Smith, ${ }^{8}$ that for PO is from Gore ${ }^{9}$ and papers cited by him, while $v_{\mathrm{NO}}$ is midway between the limits $950-970 \mathrm{~cm} .^{-1}$ reported by Mathis, Wolf, and Gallais. ${ }^{10}$ Owing to the absence of definite information regarding $r_{\text {YO }}$ for " true " single and " true " double bonds between Y and oxygen (cf. equation iii in ref. $7 a$ ), and because $\nu_{\mathrm{O}-\mathrm{N}}$ is uncertain in aliphatic amines generally (cf. Bellamy, ref. 11), Table 2 cannot be completed; nevertheless the opposite trends in $b_{\mathrm{L}}^{\mathrm{X} \mathrm{Y}}$ from $\mathrm{YX}_{3}$ to $\mathrm{OYX}_{3}$ are correctly predicted.

Transverse bond polarisabilities. Vogel ${ }^{12}$ has recorded dispersion measurements of refractivity from which $R_{\infty}$ for $\mathrm{PCl}_{3}$ and $\mathrm{OPCl}_{3}$ may be deduced as $25 \cdot 33$ and $24 \cdot 69$ c.c., respectively; from the former the total polarisability ( $b_{\mathrm{L}}^{\mathrm{P}-\mathrm{Cl}}+2 b_{\mathrm{T}}^{\mathrm{P}-\mathrm{Cl}}$ ) of the $\mathrm{P}-\mathrm{Cl}$ link is $1.004 \times 10^{-23}$ c.c. (strictly this total must include contributions due to the lone-pair electrons of the phosphorus atom; an analogous remark applies, of course, to Aroney and Le Fèvre's discussion ${ }^{3}$ of the $\mathrm{N}-\mathrm{H}$ and $\mathrm{N}-\mathrm{C}$ bonds). The apparent transverse polarisability of $\mathrm{P}-\mathrm{Cl}$ in $\mathrm{PCl}_{3}$ is therefore $0.194 \times 10^{-23}$ c.c. Since there is no clear way of disentangling

[^0]the refractivities of the $\mathrm{P}-\mathrm{Cl}$ and the PO links in phosphorus oxychloride, we assume that the ratio $b_{\mathrm{L}}^{\mathrm{P}-\mathrm{Cl}} / b_{\mathrm{T}}^{\mathrm{P}-\mathrm{Cl}}$ is the same in phosphorus trichloride and oxychloride; accordingly $b_{\mathrm{L}}^{\mathrm{P}-\mathrm{Cl}}$ in $\mathrm{OPCl}_{3}$ appears as $0.164 \times 10^{-23}$. If ( $b_{\mathrm{L}}+2 b_{\mathrm{T}}$ ) for $\mathrm{C}-\mathrm{N}$ is the same in trimethylamine as in the oxide, the values of $b_{\mathrm{L}}^{\mathrm{C}-\mathrm{N}}$ in Table 2 correspond to values of $b_{\mathrm{T}}^{\mathrm{C}-\mathrm{N}}$ of $0.07_{2}$ and $0.06_{6} \times 10^{-23}$, respectively. (In this paragraph, for want of guiding information, we presume the two transverse polarisabilities of the $\mathrm{P}-\mathrm{Cl}, \mathrm{PO}$, and NO bonds to be equal, e.g., $b_{\mathrm{T}}^{\mathrm{P}-\mathrm{Cl}}=b_{\mathrm{V}}^{\mathrm{P}-\mathrm{Cl}}$.)

Predictions of molecular polarisabilities. With the geometrical details appropriate for these molecules, their principal polarisabilities may be estimated. The $\mathrm{Cl} \cdot \mathrm{P} \cdot \mathrm{Cl}$ angles are ${ }^{4} 100 \cdot 1^{\circ}$ in phosphorus trichloride and $103 \cdot 6^{\circ}$ in the oxychloride. By symmetry the resultant dipole moment $\mu_{\text {res }}$ in each structure will act along the rotational axis, parallel to which also one of the principal molecular polarisabilities, $b_{1}$, is measured; $b_{2}$ and $b_{3}$, the two other polarisabilities, relate to directions which are mutually perpendicular, and also perpendicular to that of $b_{1}$. The angles between $\mu_{\text {res }}$ and a $\mathrm{P}-\mathrm{Cl}$ bond follow as $62^{\circ} 16^{\prime}$ in phosphorus trichloride and $65^{\circ} 10^{\prime}$ in the oxychloride. Introduction of the appropriate polarisabilities for PCl and PO therefore yields:

$$
10^{23} b_{1}{ }^{\mathrm{PCl}_{3}}=0.856 \text { and } 10^{23} b_{1}{ }^{\mathrm{OPCl}_{3}}=1.133 .
$$

From $R_{\infty}$, we know ( $b_{1}+2 b_{2}$ ), so that

$$
10^{23} b_{2}{ }^{\mathrm{PCl}_{3}}=1.078 \text { and } 10^{23} b_{2}{ }^{\mathrm{OPCl}_{3}}=0.901_{5} .
$$

In trimethylamine oxide the $\mathrm{C} \cdot \mathrm{N} \cdot \mathrm{C}$ angle is reported by Lister and Sutton ${ }^{13}$ as $109 \cdot 5^{\circ}$, i.e., within the limits ( $108^{\circ} \pm 4^{\circ}$ ) given in ref. 4 for trimethylamine itself; $\left(b_{1}+2 b_{2}\right)$ for trimethylamine is $2.299_{5}$ and for trimethylamine oxide is $2.505 \times 10^{-23}$. Calculated values follow as in Table 3.

Table 3. Predicted and found principal molecular polarisabilities.

|  | $10^{2 s} b_{1}$ calc. | $10^{23}\left(b_{2}=b_{3}\right)$ calc. | $10^{23} b_{1}$ found | $10^{23}\left(b_{2}=b_{3}\right)$ found |

* Bracketed values are obtained if $\mu$ is taken as $0.75_{3} \mathrm{D}$; see discussion above.
$\dagger$ From ref. 3.
The only seriously incorrect prediction is that for phosphorus oxychloride. Perhaps the empirical equations are inapplicable to bonds-such as PO-involving $d$-orbitals: alternatively, $1290 \mathrm{~cm} .{ }^{-1}$ may not be the appropriate frequency in this case. To obtain $b_{1}{ }^{\mathrm{OPCl}_{3}}=$ $0.902 \times 10^{-23}$ requires $\nu_{\mathrm{PO}}$ to be $964 \mathrm{~cm} .^{-1}$.

## Experimental

Materials, Methods, etc.-The two phosphorus halides were B.D.H. products, redistilled as required, fractions with b. p. $75-76^{\circ}$ (trichloride) and $106-107^{\circ}$ (oxychloride) at 760 mm . being taken. Trimethylamine oxide hydrate, prepared according to Meisenheimer, ${ }^{14}$ was dehydrated by sublimation at $150^{\circ} / 5 \mathrm{~mm}$., and stored in vacuo over phosphorus pentoxide; it had m. p. $220^{\circ}$. Benzene and dioxan were purified by refluxing them over, and then distilling them from, sodium-potassium alloy or sodium, respectively, immediately before making up solutions. Obvious precautions against moist air were taken in all transference operations; unless the dioxan solutions were kept thoroughly dry the insoluble hydrate of trimethylamine oxide was gradually precipitated and prevented electric birefringence measurements.

Apparatus, techniques, symbols used, and methods of calculation, have been as described before. ${ }^{15,16}$ Observations are recorded in Table 4 and results summarised in Table 5 . The

[^1]quantities $\Delta \varepsilon, \Delta d, \Delta n$, and $\Delta B$ are the differences found between the dielectric constants, densities, refractive indexes, and Kerr effects, respectively, of the solvents and of solutions containing weight fractions $w_{2}$ of solute. The following data apply at $25^{\circ}$ to the two solvents involved:

|  | $\varepsilon_{1}$ | $d_{1}$ | $\left(n_{1}\right)_{\mathrm{D}}$ | $p_{1}$ (c.c.) | $C$ | $H$ | $J$ | $B_{1} \times 10^{7}$ | ${ }_{8} K_{1} \times 10^{12}$ |
