267. Molecular Polarisability: Dipole Moments, Molar Kerr Constants, and Apparent Conformations of Some aw-Dichloro- and -Dibromoalkanes.

By M. ARONEY, D. IZSAK, and R. J. W. LE FÈVRE.

Dipole moments and molar Kerr constants are calculated for various rotational isomers of ten $\alpha\omega$ -dihalgenoalkanes, and compared with measurements made on solutions in carbon tetrachloride at 25°. Results are explained by the solutes' being mixtures of isomers. With dichloroethane 73% of trans- and 27% of gauche-forms appear to be present; with dibromoethane the corresponding figures are 89% and 11%. With the higher members, for which the number of possible conformations is greater, conclusions cannot be definite; specifications are given for those forms in each case which, if present together, could produce μ 's and $_{m}K$'s consistent with those found.

THIS paper deals with relations between the anisotropies of polarisability and the apparent conformations of "flexible" solute molecules at infinite dilution in non-polar media. In particular it reports an examination of ten molecules of type $[CH_2]_n X_2$ (where n = 2, 3, 4, 5, or 10, and X = Cl or Br) in carbon tetrachloride at 25°. Observations and results are summarised under usual 1 headings in Tables 1 and 2, after which their interpretations and bearings on previous data are discussed.

EXPERIMENTAL

The dihalogenoalkanes were either purified commercial samples or were prepared from the corresponding glycols (cf. Vogel²); they were redistilled, and collected at the temperatures

shown, immediately before the solutions were made up: 1,2-dichloroethane, b. p. 84°; 1,3-dichloropropane, b. p. 120-122°; 1,4-dichlorobutane, b. p. 160°; 1,5-dichloropentane, b. p. 84°/22 mm.; 1,10-dichlorodecane, b. p. 130-132°/6-7 mm.; 1,2-dibromoethane, b. p. 131°; 1,3-dibromopropane, b. p. 165-166°; 1,4-dibromobutane, b. p. 88°/16-18 mm.; 1,5-dibromopentane, b. p. 114-116°/20 mm.; 1,10-dibromodecane, m. p. 27°.

Details of procedures, apparatus, computational methods, symbols used, etc., are given in refs. 1. For pure carbon tetrachloride (*i.e.*, when $w_2 = 0$ in Table 1) at 25°, the properties indicated have values as follows: ε (dielectric constant) = 2.2270; d (density) = 1.58454; n (refractive index) = 1.4575; B (Kerr constant) = 0.070 $\times 10^{-7}$.

Previous Measurements.-Dipole-moment determinations made before 1948 are listed by Wesson³ in Tables which contain no values for 1,4-dichlorobutane, 1,5-dichloropentane, and 1,10-dichlorodecane. Since 1948 the following solution measurements (D) have been published by Ketelaar and van Meurs: 4 1,2-dibromoethane 0.94-0.95, 1,3-dibromopropane 1.98-2.00, 1,4-dibromobutane 1.92-1.95, 1,5-dibromopentane 2.24-2.27, and 1,10-dibromodecane 2.51-2.57. Only determinations made in carbon tetrachloride at 20° , as calculated from the Debye equation, are given above; however, this reference 4 lists also measurements at different temperatures in benzene, dioxan, n-hexane, cyclohexane, and in the pure liquid state. Gas measurements are recorded after 1948 as: 1,2-dichloroethane ⁵ 1.91-1.84 at 302-337° K, 1,4-dichlorobutane ⁶ 2.22 at 160-235°.

 $K (= B\lambda/n)$ for gaseous 1,2-dichloroethane at 108.5° has been reported ⁷ as 4.7 \times 10⁻¹⁵, for light of wavelength 546 mµ and a pressure of 760 mm. Molar Kerr constants of 1,2-dichloroethane and 1,2-dibromoethane (in carbon tetrachloride) have been given as $(15.7-16.0) \times 10^{-12}$ and $(17.5-17.8) \times 10^{-12}$, respectively, by Marinin ⁸-these were stated to be almost independent of temperature $(15-70^{\circ})$.

DISCUSSION

Molar Kerr Constants in Relation to Conformations.—Our approach is to calculate the "K's and the moments expected for various possible conformations and to compare the results with the corresponding observed quantities.

For each particular model considered a symmetric matrix

$$\begin{bmatrix} b_{xx} & b_{yx} & b_{zx} \\ b_{xy} & b_{yy} & b_{zy} \\ b_{xz} & b_{yz} & b_{zz} \end{bmatrix}$$

defines the molecular polarisability tensor referred to an arbitrarily selected system of cartesian co-ordinate axes X, Y, Z. The matrix is not in general diagonal: the principal

axes transformation which makes it so is effected on the Sydney University digital computer Silliac, an eigenvalue-eigenvector programme being available in the computing library. Tables 3-7 list the principal polarisabilities and their locations with respect to X, Y, Z for the structures shown.

Certain details of bond polarisabilities and of molecular geometry are required for these calculations. The anisotropic polarisabilities of C-Cl and C-Br are taken as in methyl chloride and methyl bromide (Le Fèvre and Le Fèvre, 1955, p. 300), viz; $b_L^{O-OI} =$ 0.318, $b_T^{\text{O-Cl}} = b_V^{\text{O-Cl}} = 0.220$, $b_L^{\text{O-Br}} = 0.465$, $b_T^{\text{O-Br}} = b_V^{\text{O-Br}} = 0.308$ (all as units 10^{-23} c.c.). For the C-C bond, polarisability semi-axes (viz., $b_L^{O-O} = 0.098_{a}$, $b_T^{O-O} = b_T^{O-O} = 0.027_4$) extracted from cyclohexane ⁹ are used; and for the isotropically polarisable ¹ C-H bond, $b_L^{C-H} = b_T^{C-H} = b_T^{C-H} = 0.064 \times 10^{-23} \text{ c.c.}$ The C-C-Cl, C-C-Br, and C-C-C bond angles are assumed to be 110° throughout: small deviations from this angle do not sensitively affect the calculations. Bond moments for C-Cl and C-Br are adopted as 1.86 and 1.82 D, respectively. The nomenclature followed for the various forms is that described in ref. 10, p. 560.

1,2-Dichloro- and 1,2-Dibromo-ethane.—Ainsworth and Karle¹¹ showed that for 1,2-dichloroethane, the gauche-forms are generated by rotating CH₂Cl 109° + 5° from the trans-structure; this has been accepted as such in the present work, but for $X \cdot [CH_a]_n \cdot X$ (X = Cl or Br) where n > 2, the gauche-positions are regarded as requiring 120° rotations from the trans. Computed values of the molecular polarisability semi-axes, their locations with respect to the orthogonal axes X, Y, Z, resultant dipole moments, and molar Kerr constants for the trans-, gauche-, and cis-rotational isomers are summarised in Table 3.

 $\begin{array}{ccccccc} & X & X & X & X \\ & X & C-C' & C-C' & C-C' \\ & Z & X' & 1a & 1b & 1c \end{array}$

Leybold models indicate that the *cis*-forms are sterically improbable. Reed and Lipscomb ¹² have stated that at -140° the molecule of 1,2-dichloroethane exists in the

Le Fèvre and Le Fèvre, J., 1956, 3549.

Reed and Lipscomb, Acta Cryst., 1953, 6, 45.

$$\mu$$
 (calc.) = 1.4₈ D; _mK (calc.) = 10.6₅ × 10⁻¹²,

in reasonable accord with the observed values of 1.47 D and 13.4×10^{-12} , respectively.

For 1,2-dibromoethane a mixture of the *trans*- (89%) with the *gauche*-isomer (11%) yields:

$$\mu$$
 (calc.) = 0.93 D; $_{\rm m}K$ (calc.) = 11.7₅ × 10⁻¹²,

again in reasonable accord with the observed values of 0.93 D and 13.9×10^{-12} , respectively.

1,3-Dichloro- and 1,3-Dibromo-propane.—Four rotational isomers can be predicted for each of these molecules (Formulæ 2a—d), but examination of molecular models shows that the gauche-gauche'-isomers must be extremely unstable because of steric interference between the halogen atoms. Computed values for the other three configurations are given in Table 4.

The observed values, from Table 2, are:

1,3-Dichloropropane1,3-Dibromopropane
$$\mu_{obs} = 2.07 \text{ D}; \quad \infty(mK_2) = -1.8 \times 10^{-13}.$$
 $\mu_{obs} = 1.99 \text{ D}; \quad \infty(mK_2) = -1.7 \times 10^{-13}.$

Clearly none of the three isomers 2a—c can be favoured or, alternatively, eliminated on such evidence. This is not incompatible with the spectroscopic studies by Brown and Sheppard,¹⁰ and it appears that contributions from all three are present in solution at ordinary temperatures. A marked simplification of the infrared spectra was observed on crystallisation and, from assignments of C-X stretching frequencies for *trans*- and *gauche*-dispositions and from symmetry considerations, Brown and Sheppard concluded that the solid-state isomer is the non-planar *gauche-gauche*-conformation.

1,4-Dichloro- and 1,4-Dibromo-butane.—The four conformations examined are represented by Fig. 3a—d; throughout it is assumed that the carbon skeleton remains planar. The calculations are summarised in Table 5. Observed values are:

1,4-Dichlorobutane	1,4-Dibromobutane
$\mu_{\rm obs} = 2.01 { m D}$; $_{\infty}(_{ m m}K_2) = 27.7 imes 10^{-12}.$	$\mu_{\rm obs} = 1.96 \text{ D}; \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \$

These suggest that mixtures of polar and non-polar isomers occur together in almost equal proportions, and that within the $\sim 50\%$ polar constituent, conformation 3b outweighs 3d in 1,4-dichlorobutane, but that the reverse is the case for the dibromo-analogue.

1,5-Dichloro- and 1,5-Dibromo-pentane.—Table 6 summarises the physical constants calculated for four conformations. The observed values are:

1,5-Dichloropentane1,5-Dibromopentane
$$\mu_{obs} = 2.35 \text{ D}; \ \infty(\text{m}K_2) = 34.0 \times 10^{-12}.$$
 $\mu_{obs} = 2.30 \text{ D}; \ \infty(\text{m}K_2) = 51.7 \times 10^{-12}.$

These cannot be accounted for by a mixture of *trans-trans-, trans-gauche*, and *gauche-gauche*-forms alone; this indicates that, unlike the 1,3-dihalogenopropanes, there is participation in the mixture of isomers of the now sterically allowable *gauche-gauche'*-form.

1,10-Dichloro- and 1,10-Dibromo-decane.—Computed values for the four conformations considered (analogous to Fig. 3a--d) are summarised in Table 7. Observed values are:

1,10-Dichlorodecane	1,10-Dibromodecane
$\mu_{\rm obs} = 2.61 \text{ D}; \ \ _{\infty}(_{\rm m}K_2) = 50.3 \times 10^{-18}.$	$\mu_{\rm obs} = 2.61 { m D}; \ \ _{\infty}({ m m}K_2) = 95.0 imes 10^{-13}.$

TABLE 6. 1,5-Dichloropentane

If the assumption is valid that the carbon chain is coplanar, then the mixture of isomers appears to contain a 3:1 mixture of polar: non-polar constituents; in both cases the trans-gauche-conformation seems to predominate.
