## 1024. Bonding in Tervalent Rhenium $\operatorname{Re}_{3} \mathrm{X}_{9+n}{ }^{n-}$ Anions

By J. E. Fergusson, B. R. Penfold, M. Elder, and B. H. Robinson

A semiquantitative bonding scheme is presented for the trinuclear tervalent rhenium halogeno-anions. The bonding is divided into $\sigma$ - and $\pi$-components. The principal structural features and magnetic properties of the anions can be explained by the theory.

The recent developments in the chemistry of tervalent rhenium show that, under certain experimental conditions, salts containing the trinuclear halogeno-anions $\mathrm{Re}_{3} \mathrm{Cl}_{12}{ }^{3-}$, $\mathrm{Re}_{3} \mathrm{Cl}_{11}{ }^{2-}, \mathrm{Re}_{3} \mathrm{Br}_{12}{ }^{3-}, \mathrm{Re}_{3} \mathrm{Br}_{11}{ }^{2-}$, and $\mathrm{Re}_{3} \mathrm{Br}_{10}{ }^{-1,1-7}$ can be isolated, as well as neutral complexes $\mathrm{Re}_{3} \mathrm{X}_{9}$ (unidentate) ${ }_{3}$ and $\mathrm{Re}_{3} \mathrm{X}_{6}$ (bidentate) ${ }_{3}{ }^{7-9}$ The structures of these compounds, and of the entities $\mathrm{Re}_{3} \mathrm{Cl}_{9}$ and $\mathrm{Re}_{3} \mathrm{Br}_{9}$, have been shown from crystal structure ${ }^{1-3,6,10,11}$ and spectral ${ }^{3,8}$ evidence to be based on a triangle of bonded rhenium atoms. The Table presents relevant structural data at present available on certain of the trinuclear species.

A molecular orbital approach to the bonding in $\mathrm{Re}_{3} \mathrm{Cl}_{12}{ }^{3-}$ was made by Cotton and Haas. ${ }^{12}$ Their method is also of general applicability to other cluster structures, $\mathrm{M}_{6} \mathrm{X}_{8}{ }^{4+}$ ( $\mathrm{M}=\mathrm{Mo}$ or W ) and $\mathrm{M}_{6} \mathrm{X}_{12}{ }^{2+}(\mathrm{M}=\mathrm{Nb}$ or Ta$)$, but was not specifically used to explain the fact that the metal-metal bonds are much shorter in the trimeric structures than in the cage structures. Bearing in mind these very short $\operatorname{Re}-\operatorname{Re}$ bonds, we present a different approach.*

Bond lengths $(\AA)$ and angles in trinuclear rhenium species

|  | $\mathrm{Re}_{3} \mathrm{Cl}_{12}{ }^{3-2}$ | $\mathrm{Re}_{3} \mathrm{Cl}_{11}{ }^{2-13}$ | $\mathrm{Re}_{3} \mathrm{Br}_{11}{ }^{2-10}$ | $\mathrm{Re}_{3} \mathrm{Cl}_{9}{ }^{11}$ | $\mathrm{Re}_{3} \mathrm{Br}_{9}{ }^{6}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{Re}-\mathrm{Re}$ | $2 \cdot 48$ | 2-48, $2 \cdot 43$ * | 2-49, $2 \cdot 43$ * | $2 \cdot 49$ | $2 \cdot 465$ |
| Re-X (terminal in-plane) | 2.52 | 2.57 | $2 \cdot 72$ | (2-66) |  |
| $\mathrm{Re}-\mathrm{X}$ (terminal off-plane) | $2 \cdot 36$ | 2.30, 2.29* | 2.48, 2.38* | $2 \cdot 40,2 \cdot 29$ | $2 \cdot 45$ |
| $\mathrm{Re}-\mathrm{X}$ (bridge) | $2 \cdot 39$ | $2 \cdot 35$ | $2 \cdot 54$ | $2 \cdot 46$ | $2 \cdot 54$ |
| $\mathrm{X}-\mathrm{Re}-\mathrm{X}$ (terminal off-plane). | $158{ }^{\circ}$ | $158^{\circ}, 151^{\circ} *$ | $159^{\circ}, 134^{\circ}$ * | $163{ }^{\circ}$ | $155^{\circ}$ |
| $\mathrm{Re}-\mathrm{X}-\mathrm{Re}$ (bridge) | $62^{\circ}$ | $62^{\circ}$ | $58^{\circ}$ | $61^{\circ}$ | $58^{\circ}$ |

* Values associated with the halogen-deficient Re atom.

The bonding in $\mathrm{Re}_{3} \mathrm{Cl}_{12}{ }^{3-}$ can be resolved into two components, viz., a $\sigma$-bond framework and a $\pi$-molecular orbital encompassing the triangle of rhenium atoms.

The $\sigma$-bond framework can be considered either as a distorted pentagonal bipyramid ${ }^{3}$ of five chlorine and two rhenium atoms around each rhenium, or more generally, as $\sigma$-molecular orbitals incorporating two $\mathrm{Re}-\mathrm{Re}$ bonds and five $\mathrm{Re}-\mathrm{Cl}$ bonds for each rhenium. In the former case the hybrid scheme would be $d^{3} s p^{3}$ (using $d_{z^{2}}, d_{x^{2}-y^{2}}$, and $d_{x y}$ orbitals in $D_{5 h}$ symmetry). (The Figure gives the arrangement of axes with respect to the bonds.) This involves a postulate of bent bonds, which is not unreasonable when it is taken into account that each bonded pair of rhenium atoms subtends an angle of $60^{\circ}$ at its bridging chlorine atom. The bonds from bridging chlorines must therefore be considerably bent.

[^0]The $\sigma$-bond molecular-orbital description considers the local symmetry around each rhenium as $C_{2 v}$, and the seven bonds transform as the reducible representation $\Gamma_{\sigma}=$ $4 A_{1}+B_{1}+2 B_{2}$. The orbitals of the metal that transform as the irreducible components of $\Gamma_{\sigma}$ are: $A_{1}: p_{x}, d_{z^{2}}, s, d_{x^{2}-y^{2}} ; B_{1}: p_{z}, d_{x z} ; B_{2}: p_{x}, d_{x y}$. The $\sigma$-bonds are made up of two $\operatorname{Re}-\mathrm{Re}$ bonds, $\Gamma_{\sigma} \mathrm{Re}-\mathrm{Re}=A_{1}+B_{2}$, and five $\mathrm{Re}-\mathrm{Cl}$ bonds, $\Gamma_{\sigma}^{\mathrm{Re}-\mathrm{Cl}}=3 A_{1}+$ $B_{1}+B_{2}$. From a consideration of the disposition of the orbitals listed above, relative

Continuous lines represent lines of closest approach between bonded atoms, and broken lines are directions of pentagonal bipyramid hybrids
to these bonds, we have selected the following sets: $\operatorname{Re}-\operatorname{Re}$ bonds $A_{1}: s ; B_{2}: d_{x y} ; \operatorname{Re}-\mathrm{Cl}$ bonds $A_{1}: p_{x}, d_{z^{2}}, d_{x^{2}-y^{2}} ; B_{1}: p_{z} ; B_{2}: p_{y}$. Molecular orbitals of the ligands, which transform as the above irreducible representations, can easily be determined by use of group theoretical methods. ${ }^{14}$

This leaves two unused atomic orbitals on each metal, viz., $d_{y z}$, which does not appear in the above, and $d_{x z}$, which was not used. The same two orbitals are unused in the pentagonal bipyramid hybrid $\sigma$-bonding. The total of six atomic orbitals can be combined by the LCAO-MO approach, to give six $\pi$-molecular orbitals, three bonding ( $A_{1}{ }^{\prime}+E^{\prime}$ ) and three antibonding $\left(A_{2}{ }^{\prime}+E^{\prime}\right)$ in the point group symmetry $D_{3} h^{15}$

The complete structure $\mathrm{Re}_{3} \mathrm{Cl}_{12}{ }^{3-}$ has therefore a possible total of eighteen $\sigma$ - and three $\pi$-bonding orbitals. If we consider that each terminal halogen donates two electrons, and each bridging halogen donates four, this will leave three $\sigma$ - and three $\pi$-bonding orbitals to accommodate the $d$-electrons of the metal atoms. Each rhenium atom in the anion has a formal charge of +3 and hence will have the $d^{4}$ configuration. The total of twelve $d$-electrons will therefore be successfully accommodated in the remaining bonding molecular orbitals.

This description accounts for the short metal-metal bond $(0.3 \AA$ shorter than in rhenium metal) in terms of one $\sigma$ - and one $\pi$-bond per $\operatorname{Re}-\operatorname{Re}$ bond. In addition, the bonding scheme accounts for the observed diamagnetism of the tervalent anions. It would also account for the one unpaired electron per triangle found in the neutral quadrivalent $\mathrm{Re}_{3} \mathrm{Cl}_{12}{ }^{16}$ There are here only three electrons to distribute among the $A_{1}{ }^{\prime}$ and $E^{\prime}$ $\pi$-molecular orbitals.

It is clear that the bonding in the $\mathrm{Re}_{3} \mathrm{X}_{11}{ }^{2-}$ anion is basically the same as for $\mathrm{Re}_{3} \mathrm{Cl}_{12}{ }^{3-}$ the only difference being that one $\sigma$-orbital on one rhenium atom (centrifugally directed from the triangle) is vacant. However, comment is necessary on the observation that the two $\operatorname{Re}-\mathrm{Re}$ bonds involving the halogen-deficient metal are significantly shorter than the other one.

The orbital on the halogen-deficient rhenium atom most likely to be affected by the

8 P
loss of the terminal-in-plane halogen is the $p_{x}$. This orbital (in $C_{2 v}$ symmetry) transforms as the $A_{1}$ representation and may be considered to form a hybrid with, say, the $s\left(A_{1}\right)$ orbital of the same rhenium atom. The $s p$-hybrid pointing into the triangle will be expected to give greater overlap than a simple $s$-orbital in the metal-metal $\sigma$-bonding, leading to a shortening of the two bonds to the halogen-deficient metal atom. This process would be assisted by the increased positive charge developed on this atom.

This mixing of the $p_{x}$ and s-orbitals is not ruled out even for $\mathrm{Re}_{3} \mathrm{Cl}_{12}{ }^{3-}$. However, whereas it may give stronger bonding in an already tightly bound metal triangle it would not necessarily, by replacing a $p_{x}$ orbital with an $s p$-hybrid, give much improvement for the terminal-in-plane $\mathrm{Re}-\mathrm{Cl}$ bond. Any advantage is in fact apparently lost since, for steric reasons, these $\mathrm{Re}-\mathrm{Cl}$ bonds are unusually long.

This explanation offered for the shortening of $\operatorname{Re}-\mathrm{Re}$ bonds in $\mathrm{Re}_{3} \mathrm{X}_{11}{ }^{2-}$ leads naturally to an enquiry into the result of removing further in-plane terminal halogen atoms from the trimeric system. No dimensions are yet available for any $\mathrm{Re}_{3} \mathrm{X}_{10}{ }^{-}$ion, and $\mathrm{Re}_{3} \mathrm{Cl}_{9},{ }^{11}$ with its strong intermolecular interactions possesses, as expected, the same size $\mathrm{Re}_{3}$ triangle as in $\mathrm{Re}_{3} \mathrm{Cl}_{12}{ }^{3-}$. The $\mathrm{Re}_{3} \mathrm{Br}_{9}$ entity in (QnH) ${ }_{2} \mathrm{Re}_{4} \mathrm{Br}_{15}{ }^{6}$, however, apparently exists in comparative isolation in the crystal and therefore should reveal whether $\mathrm{Re}-\mathrm{Re}$ bond shortening is cumulative. (There will, of course, be no charge effect in the symmetrical $\mathrm{Re}_{3} \mathrm{Br}_{9}$ to contribute to such shortening.) In fact, the mean $\operatorname{Re}-\operatorname{Re}$ length of $2.465 \AA$ is not significantly shorter than any of the " long" bonds in species so far examined, but neither is it significantly longer than $2 \cdot 45 \AA$, the mean length in both $\operatorname{Re}_{3} \mathrm{X}_{11}{ }^{2-10}$ anions. The evidence then is that in $\operatorname{Re}_{3} \mathrm{X}_{11}{ }^{2-}$ the limit to the reduction in overall size of the $\operatorname{Re}_{3}$ triangle has been reached. Clearly, a structure analysis of a salt of $\mathrm{Re}_{3} \mathrm{Br}_{10}{ }^{-}$is much to be desired. The detailed dimensions of $\mathrm{Re}_{3} \mathrm{Br}_{12}{ }^{3-}$ would also be highly relevant, and a structure analysis of $\mathrm{Cs}_{3} \mathrm{Re}_{3} \mathrm{Br}_{12},{ }^{10}$ at present in progress in this laboratory, should provide these.
