

# Tertiary phosphine ligand-exchange reactions involving the $M\equiv M$ quadruply bonded complexes $M_2Cl_4L_4$ , where $L = PMe_3, PEt_3, PBu^n_3$ or $PMe_2Ph$ \*

Malcolm H. Chisholm and Jacqueline M. McInnes

Department of Chemistry, Indiana University, Bloomington, IN 47405, USA

The reactions between  $M_2Cl_4L_4$  complexes and an excess of  $L$  or  $L'$  ( $PMe_3, PEt_3, PBu^n_3, PMe_2Ph$  or  $PMePh_2$ ) have been studied in  $[^2H_8]$ toluene by  $^{31}P\{-^1H\}$  NMR spectroscopy. The substitutions proceed in a stepwise manner wherein  $L'$  displaces  $L$ , except for  $L' = Me_2PCH_2CH_2PMe_2$  (*dmpc*) which yields  $Mo_2Cl_4(dmpc-P)_4$ . No tertiary phosphine in this series is capable of displacing  $PMe_3$  from a  $M_2Cl_4(PMe_3)_4$  complex but by spin magnetization transfer the degenerate exchange involving  $Mo_2Cl_4(PMe_3)_4$  and  $PMe_3$  (added in excess) can be detected. The complexes  $Mo_2Cl_4(PMe_3)_4$  and  $Mo_2Cl_4(PEt_3)_4$  in benzene showed no  $PMe_3$  for  $PEt_3$  scrambling at  $+50^\circ C$  over several days despite the fact that  $Mo_2Cl_4(PMe_3)_{4-n}(PEt_3)_n$  where  $n = 2$  or  $3$ , are kinetically inert to ligand redistribution. In the presence of  $[^2H_5]$ pyridine  $Mo_2Cl_4(PMe_3)_4$  and  $Mo_2Cl_4(PEt_3)_4$  underwent tertiary phosphine scrambling at  $25^\circ C$  and in neat  $[^2H_5]$ pyridine  $Mo_2Cl_4(PMe_3)_4$  revealed the formation of an equilibrium concentration of  $Mo_2Cl_4(PMe_3)_3(py)$  ( $py =$  pyridine) and free  $PMe_3$ . Under similar conditions  $Mo_2Cl_4(PEt_3)_4$  yielded an equilibrium mixture of  $Mo_2Cl_4(PEt_3)_3(py)$  and  $Mo_2Cl_4(PEt_3)_2(py)_2$  and free  $PEt_3$ . From kinetics the  $\Delta H^\ddagger$  values are positive in the range  $+24$  to  $+34$  kcal mol $^{-1}$  and the  $\Delta S^\ddagger$  values range from  $+12$  to  $+28$  cal K $^{-1}$  mol $^{-1}$ . Collectively the data reported are consistent with an interchange dissociative mechanism,  $I_d$ , wherein  $M-P$  bond breaking contributes significantly to the rate-determining step with related values of  $\Delta H^\ddagger$  being larger for  $M = W$  than  $M = Mo$ . The rate dependence on the entering ligand is clearly evident from temperature-dependent studies and leads to varying  $\Delta S^\ddagger$  values. The  $I_d$  mechanism is proposed to involve pre-equilibria between  $M_2Cl_4L_4$  and the entering  $L'$  in an axial site followed by rate-determining  $M-L$  displacement. In neat  $[^2H_5]$ pyridine this may be viewed as a solvent-assisted displacement. The present results are discussed in terms of earlier studies from which researchers inferred a simple dissociative process,  $D$ , involving  $M-PR_3$  bond rupture as the first and rate-determining step.

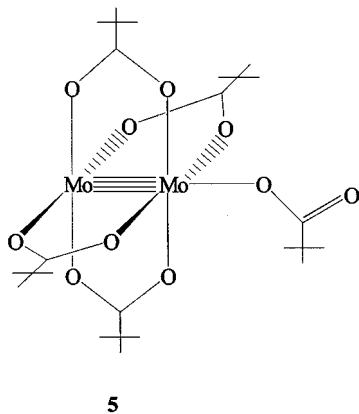

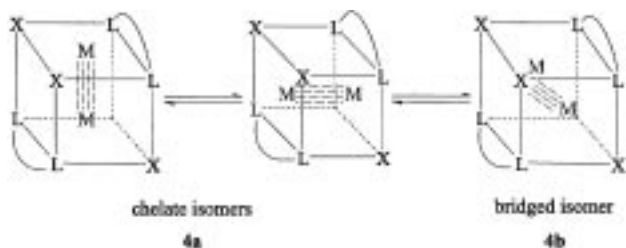

Compounds containing multiple bonds between metal atoms comprise an important class of species in modern co-ordination chemistry.<sup>1</sup> The structures and bonding in these complexes have been extensively studied as have their attendant spectroscopies. Also the redox reactivity of the dinuclear center has proved to be of interest in terms of developing multielectron substrate activation.<sup>2</sup> Within this class of compounds those containing  $M\equiv M$  quadruple bonds are particularly noteworthy as their discovery led to the recognition of the  $\delta$  bond, a bond not found in main group chemistry. Compounds with  $M\equiv M$  quadruple bonds without exception contain a  $M-M$  valence configuration  $\sigma^2\pi^4\delta^2$  where only one  $\delta$  orbital is used in  $M-M$  bonding. That is to say they are diamagnetic and the other  $\delta$  type  $M-M$  orbital is used in metal-ligand bonding. Thus these complexes have two square-planar  $ML_4$  units joined by the  $M\equiv M$  quadruple bond in an eclipsed manner as depicted in **1**. The eclipsed geometry is the one that allows for the formation of the  $\delta^2$  bond and members of this series of  $d^4-d^4$  dinuclear complexes include  $M_2(\mu-O_2CR)_4$ ,  $M_2(\text{porphyrin})_2$ , where  $M = Mo$  and  $W$ , and  $R =$  alkyl or aryl, and  $M_2X_8^{n-}$  where  $M = Mo$  or  $W$ ,  $X =$  halide,  $n = 4$  and  $M = Tc$  or  $Re$ ,  $X =$  halide and  $n = 2$ .<sup>1</sup> In addition for  $M = Mo$  and  $W$  there is an important group of complexes of the formula  $M_2X_4L_4$  where  $X =$  alkyl, alkynyl or halide and  $L =$  a neutral donor ligand such as a tertiary phosphine  $PR'_3$  or pyridine,  $py$ . These typically adopt a structure depicted by **2** which is presumably favored by steric considerations. The use of chelating diphosphines such as  $Ph_2PCH_2CH_2PPh_2$  and related arsines leads to so-called  $\alpha$  and  $\beta$  isomers shown in **3a** and **3b**, respectively.<sup>3</sup> The latter have attracted

certain attention because the  $\alpha$  isomer is a kinetic product of the reaction between  $M_2X_8^{4-}$  and the chelating phosphine or arsine and the  $\beta$  isomer is the thermodynamic product. In the  $\beta$  isomer there is often a twist about the  $M-M$  axis so that the two four-co-ordinate metal atoms are not eclipsed. The latter phenomenon has drawn attention with respect to the energetics of

\* Dedicated to Professor Fred Basolo, from whom we learned much about substitution reactions at metal centers, on the occasion of his 75th birthday.

Non-SI unit employed: cal = 4.184 J.

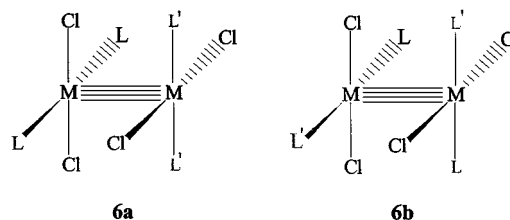

the  $\delta$ - $\delta$  interactions and the assignment of the  $\delta \rightarrow \delta^*$  electronic transitions.<sup>4</sup> The conversion of the  $\alpha$  into the  $\beta$  isomers, **3a** and **3b**, has also been extensively studied and evidence in favor of an 'internal flip' mechanism has been presented.<sup>5</sup> In this mechanism the M-M axis is reoriented about one of three positions within the pseudo-cubic arrangement of ligands as shown in **4**.

Remarkably little attention has been paid to the mechanisms of ligand substitution reactions at  $M \equiv M$  quadruply bonded complexes. In comparing the reactivity of  $M_2(O_2CR)_2$ - $(MeCN)_4^{2+}$  complexes we noted that the MeCN ligands were extremely labile for  $M = Mo$  compared to  $M = Rh$  and we suggested that this might be due to electronic factors associated with their respective M-M electronic configurations:  $M = Mo$ ,  $\sigma^2\pi^4\delta^2$ ; vs.  $M = Rh$ ,  $\sigma^2\pi^4\delta^2\delta^*\pi^*4$ .<sup>6</sup> The latter configuration may be viewed as electronically saturated in a similar manner to octahedral cobalt(III) and rhodium(III) complexes that have a  $t_{2g}^6$  electronic configuration and are chemically inert. Their substitution reactions proceed *via* dissociative or interchange dissociative mechanisms.<sup>7</sup> By contrast the  $Mo_2^{4+}$  center with its electronic configuration  $\sigma^2\pi^4\delta^2$  has low-lying empty metal d-based molecular orbitals available for nucleophilic attack. The lability of  $Mo_2(O_2CR)_4$  complexes has also been noted in their facile carboxylate exchange reactions in solution<sup>6,8</sup> and the  $Mo_2(O_2CBu^t)_5^-$  anion, which has the solid-state molecular structure shown in **5**, is fluxional on the NMR time-scale at room temperature in  $[^2H_8]$ toluene.<sup>9</sup>

While we were inclined to view the lability of the  $Mo_2^{4+}$  center in terms of its ability to enter into associative exchange processes with ligands such as carboxylates which have additional lone pairs, we were aware of the work of Andersen and co-workers<sup>10</sup> who had studied the phosphine exchange reactions shown in equation (1), where  $L = PMe_3$  or  $PMe_2Ph$ . These

workers also examined the reaction between  $Mo_2Me_4(PMe_2Ph)_4$  and  $PMe_3$  and  $PEt_3$  and found substitution of  $PMe_2Ph$  by  $PMe_3$  but not by  $PEt_3$ .<sup>10a</sup> [They also examined the reaction between  $Mo_2X_2(O_2CBu^t)_2(PMe_2Et)_2$  ( $X = CH_2CMe_3$  or  $OSiMe_3$ ) and  $PMe_3$  and determined  $\Delta H^\ddagger = 22.2$  and  $24.7$  kcal  $mol^{-1}$  for  $X = CH_2Bu^t$  and  $OSiMe_3$ , respectively, with  $\Delta S^\ddagger = 15$  cal  $K^{-1} mol^{-1}$  in both instances.<sup>10b</sup>] From studies of the kinetics of reaction (1) with an excess of  $L$  they found that the reaction was first order in  $[Mo_2]$  and zeroth order in  $[L]$  when  $L$  was

present in 10–30 mole excess. They observed no rate dependence on the entering ligand at  $-50^\circ C$  in  $[^2H_8]$ toluene and for  $L = PMe_2Ph$  they determined  $\Delta H^\ddagger = 21$  kcal  $mol^{-1}$  and  $\Delta S^\ddagger = 18$  cal  $K^{-1} mol^{-1}$ . From a comparison of reactions involving  $Mo_2Me_4(PEt_3)_4$  and  $Mo_2Me_4(PMe_2Ph)_4$  with  $PMe_3$  they observed a rate dependence on the leaving group. These observations led Andersen and co-workers,<sup>10a</sup> to conclude that the substitution of one tertiary phosphine by another was proceeding by a dissociative process and that it was favored when a bulky phosphine was replaced by a less bulky phosphine at the  $Mo_2^{4+}$  center.

Clearly the conclusions drawn by us, based only on qualitative substitutional behavior, are in opposition to the quantitative studies of Andersen and co-workers. Being mindful 'to never trust in science to the principle of exclusion',<sup>11</sup> we have now examined the reactions of phosphine interchange (2), in

$[^2H_8]$ toluene, where  $M = Mo$  or  $W$ ,  $L = PEt_3$ ,  $PBu^t_3$  or  $PMe_2Ph$  and  $L' = PMe_3$ ,  $PMe_2Ph$ ,  $PMePh_2$ ,  $Me_2PCH_2CH_2PMe_2$  (=dmpe) or pyridine. We have also examined the degenerate exchange reaction where  $L = L'$  and studied the reactions between  $Mo_2Cl_4L_4$  and  $Mo_2Cl_4L'_4$  in both toluene and pyridine. From the results of the present studies we suggest that the phosphine exchange reactions (2) do not proceed *via* a simple dissociative mechanism but rather by an interchange dissociative mechanism wherein the entering phosphine is within the co-ordination sphere of the  $M_2^{4+}$  center.

## Results and Discussion

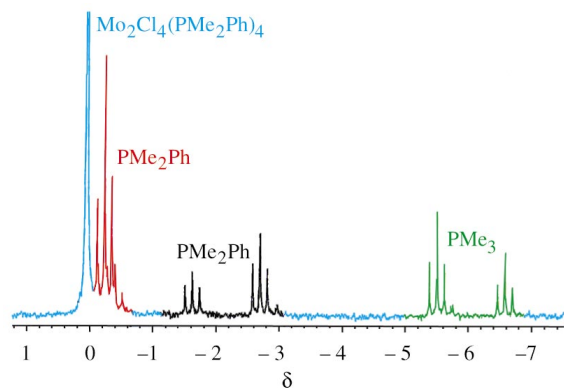

### General procedures

Studies of reactions (2) were monitored by  $^{31}P$ - $\{^1H\}$  NMR spectroscopy. The samples of  $Mo_2Cl_4L_4$  were prepared in a helium filled dry-box. The sample was weighed and dissolved in 600  $\mu l$   $[^2H_8]$ toluene in a J. Young<sup>®</sup> NMR tube. In the case of  $PMe_3$ , which is very volatile, 15 equivalents were added employing a gas-line manifold. Other  $L'$  were added by microliter syringe from stock solutions in  $[^2H_8]$ toluene. No new compounds of formula  $M_2Cl_4L_4 - nL'_n$  were isolated in this study but they were characterized by their  $^{31}P$ - $\{^1H\}$  NMR spectra and with simulated spectra. (Compounds of this type have been isolated and fully characterized previously.<sup>12</sup>)

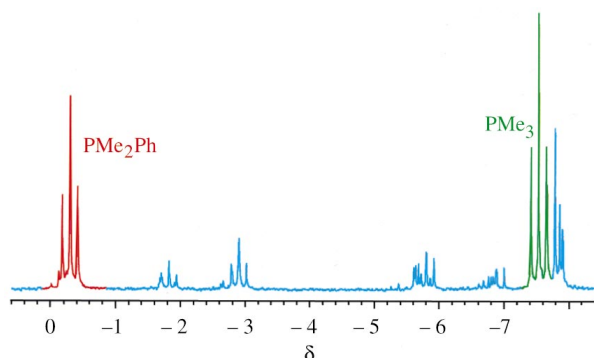

In studies of phosphine substitution (2) we monitored the disappearance of the  $^{31}P$  signal due to  $M_2Cl_4L_4$ . In most instances the stepwise appearance of  $Mo_2Cl_4L_3L'$ ,  $Mo_2Cl_4L_2L'_2$ ,  $Mo_2Cl_4LL'_3$  and  $Mo_2Cl_4L'_4$  could be seen in addition to the liberation of  $L$ . A  $Mo_2Cl_4L_2L'_2$  compound can exist in one of two isomeric forms as shown in **6a** and **6b**. Compounds **6a** are characterized by  $A_2B_2$  spin systems whereas **6b** are  $AA'BB'$  and, in the case of  $M = W$ , the spin system is further complicated by  $^{183}W$ ,  $I = \frac{1}{2}$ , 14.3% natural abundance. The reactions have been monitored as a function of the excess of  $L'$  (15–30 equivalents) and as a function of temperature.

At this point it is worth commenting on some specific aspects of these studies.

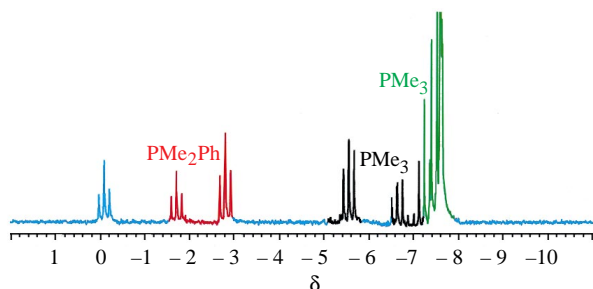

**$Mo_2Cl_4(PMe_2Ph)_4 + PMe_3$ .** Within the temperature range 35 to  $60^\circ C$  the formation of the complex  $Mo_2Cl_4(PMe_2Ph)_3(PMe_3)$  is clearly evident in this reaction as shown in Fig. 1. The

**Fig. 1** The  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectrum of  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_3(\text{PMe}_3)$ :  $^2J_{\text{PP}} = 174$ ,  $^3J_{\text{PP}} = 19$  Hz

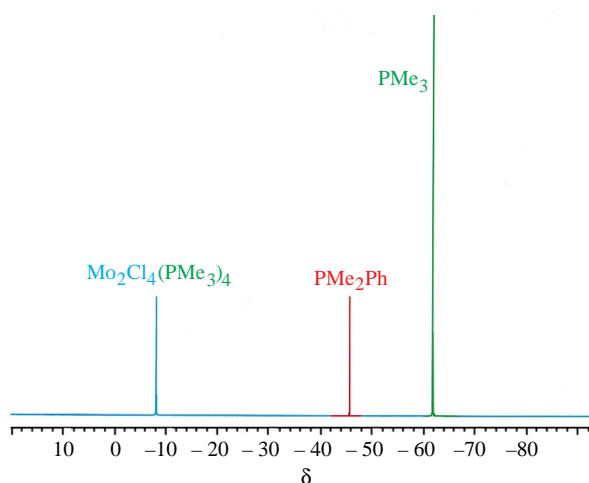

**Fig. 2** The  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectrum of  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_2(\text{PMe}_3)_2$ ,  $\text{A}_2\text{B}_2$  isomer:  $^3J_{\text{AB}} = 19$  Hz

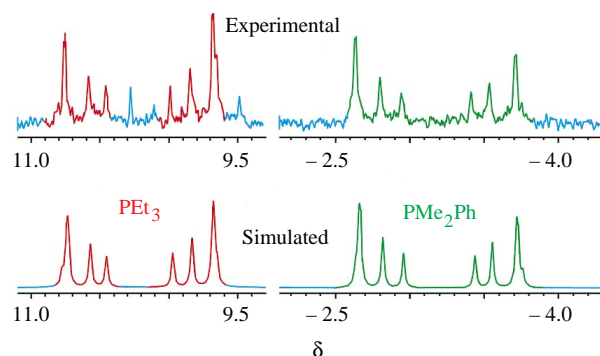

**Fig. 3** The  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectrum of  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})(\text{PMe}_3)_3$ :  $^2J_{\text{PP}} = 174$ ,  $^3J_{\text{PP}} = 19$  Hz

starting complex  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_4$  appears as a singlet and the formation of  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_3(\text{PMe}_3)$  is noted by a  $\text{PMe}_2\text{Ph}$  triplet close in chemical shift to that of the starting complex due to the two mutually *trans*  $\text{PMe}_2\text{Ph}$  ligands. The other molybdenum center has *trans*  $\text{Mo-PMe}_3$  and  $\text{Mo-PMe}_2\text{Ph}$  groups with the former being upfield of the latter. Each  $^{31}\text{P}$  nucleus gives rise to a doublet of triplets due to  $^{31}\text{P}\text{-}^{31}\text{P}$  coupling and as can be seen from Fig. 1 the doublet of triplets shows some second-order character as the chemical shift separation of the  $\text{Mo-PMe}_3$  and  $\text{Mo-PMe}_2\text{Ph}$   $^{31}\text{P}$  nuclei differ by only *ca.* 4 ppm. The  $^{31}\text{P}$  NMR spectrum has been simulated by GNMR Version 3.6 employing the  $J_{\text{pp}}$  values listed in the figure caption.

With time the signals due to  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_3(\text{PMe}_3)$  disappear as those due to  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_2(\text{PMe}_3)_2$  grow in. These are shown in Fig. 2. At this point no starting complex  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_4$  remains and free  $\text{PMe}_2\text{Ph}$  and  $\text{PMe}_3$  are both present (not shown in Fig. 2). The signals shown in red and green are due to the  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_2(\text{PMe}_3)_2$  complex and conform to an  $\text{A}_2\text{B}_2$  spin system indicating the formation of a compound of type **6a**. Other resonances shown in Fig. 2 represent  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_3(\text{PMe}_3)$  (as described before) and  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})(\text{PMe}_3)_3$ . The third substitution product  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})(\text{PMe}_3)_3$  is shown in Fig. 3 and has features

**Fig. 4** The  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectrum of the fourth substitution product  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$  and free  $\text{PMe}_2\text{Ph}$  and  $\text{PMe}_3$

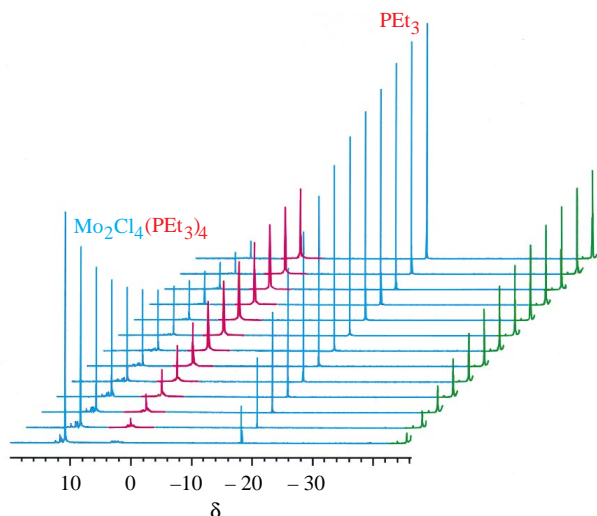

**Fig. 5** Experimental (top) and simulated (bottom)  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectra of  $\text{W}_2\text{Cl}_4(\text{PEt}_3)_2(\text{PMe}_2\text{Ph})_2$ ,  $\text{AA}'\text{BB}'$  isomer:  $^2J_{\text{PP}} = 144$ ,  $^3J_{\text{PP}} = 28$  Hz. The observed resonances shown in blue arise from  $\text{W}_2\text{Cl}_4(\text{PEt}_3)(\text{PMe}_2\text{Ph})_3$

similar to that described for the first substitution complex, namely two 'leaning' doublets of triplets and one triplet due to the mutually *trans*  $\text{Me}_3\text{P-Mo-PMe}_3$  phosphorus nuclei. The latter resonance is close and partially overlaps with the  $^{31}\text{P}$  signal of the product  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$ . Confirmation of these assignments was obtained by  $^{31}\text{P}\{-^1\text{H}\}\text{-}^{31}\text{P}\{-^1\text{H}\}$  correlation spectroscopy (COSY). The final spectrum is shown in Fig. 4 and is again simple consisting of a singlet due to  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$  along with the singlets due to free  $\text{PMe}_3$  and the displaced  $\text{PMe}_2\text{Ph}$ .

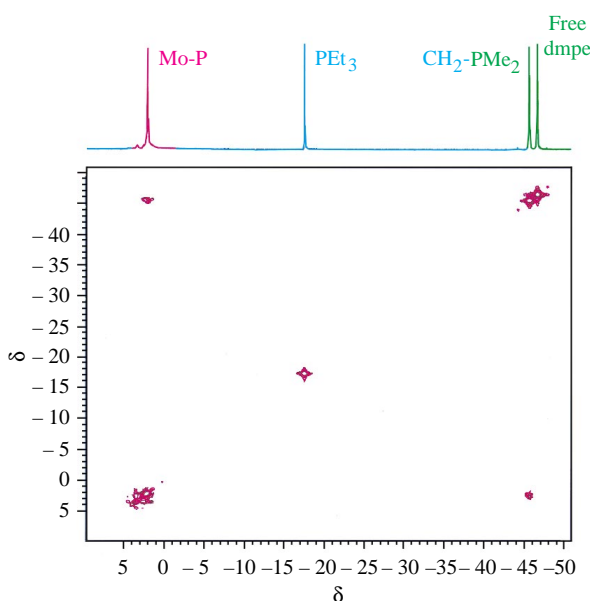

The reactions between  $\text{M}_2\text{Cl}_4(\text{PEt}_3)_4$  with  $\text{PMe}_2\text{Ph}$  proceed in a similar stepwise manner but the complexes  $\text{M}_2\text{Cl}_4(\text{PEt}_3)_2(\text{PMe}_2\text{Ph})_2$  are of the type **6b** and as shown in Fig. 5 this gives rise to two sets of multiplets which are second order, each being half of an  $\text{AA}'\text{BB}'$  spin system.

The most plausible explanation for the formation of isomer **6a** (the  $\text{A}_2\text{B}_2$  spin system, Fig. 2) in reaction (2) employing  $\text{L}' = \text{PMe}_3$  and the formation of **6b**, when  $\text{L}' = \text{PMe}_2\text{Ph}$ , is that the *trans* effect of  $\text{PMe}_3 > \text{PMe}_2\text{Ph}$ <sup>13</sup> whereas in the substitution of  $\text{PEt}_3$  by  $\text{PMe}_2\text{Ph}$  we obtain the thermodynamic isomer based on relief of steric strain. Note that in the presence of an excess of  $\text{PMe}_2\text{Ph}$ , even if the *trans* effect of  $\text{PEt}_3 > \text{PMe}_2\text{Ph}$ , the second observable product would be  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_2(\text{PEt}_3)_2$  having the configuration **6b**.

The reactions between  $\text{Mo}_2\text{Cl}_4\text{L}_4$  ( $\text{L} = \text{PEt}_3$  or  $\text{PMe}_2\text{Ph}$ ) and  $\text{Me}_2\text{PCH}_2\text{CH}_2\text{PMe}_2$  in [ $^2\text{H}_8$ ]toluene were unique amongst the series studied in that we did not observe a stepwise substitution but rather saw the formation of a compound that we formulate as  $\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4$  as the complex  $\text{Mo}_2\text{Cl}_4\text{L}_4$  decreases in concentration. The progress of a typical reaction is shown in Fig. 6. Regrettably we were not able to isolate the compound

**Fig. 6** The  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectrum of  $\text{Mo}_2\text{Cl}_4(\text{PET}_3)_4$  with excess of dmpe at  $5^\circ\text{C}$  over 8 h. The formation of  $\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4$  is seen by the growth of the red (co-ordinated) and green (dangling)  $^{31}\text{P}$  signals

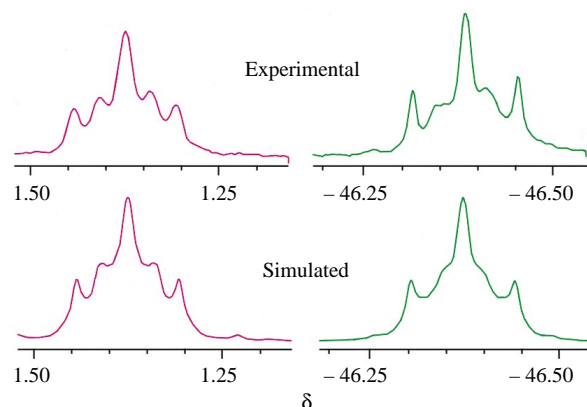

**Fig. 7** The  $^{31}\text{P}\{-^1\text{H}\}\text{-}^{31}\text{P}\{-^1\text{H}\}$  COSY NMR spectrum of  $\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4$  at  $25^\circ\text{C}$

formulated as  $\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4$  by bench-top reaction procedures because a subsequent reaction leads to an insoluble dark blue material. Upon heating the complex formulated as  $\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4$  in  $[\text{D}_6]\text{toluene}$  at  $50^\circ\text{C}$  in the presence of an excess of dmpe and the liberated L (L =  $\text{PET}_3$  or  $\text{PMe}_2\text{Ph}$ ), the solution becomes pale orange and by  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectroscopy no simple Mo-containing compound could be formulated. In the presence of an excess of dmpe it seems likely that the  $\text{M}\equiv\text{M}$  bond is cleaved upon heating. We must therefore confine our remarks to (i) examining the evidence for the existence of  $\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4$  and (ii) the kinetic data pertaining to its formation.

The  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectrum of  $\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4$  formed in the reaction between  $\text{Mo}_2\text{Cl}_4(\text{PET}_3)_4$  and an excess (15 equivalents) of dmpe is shown in Fig. 7. Note that the  $^{31}\text{P}\{-^1\text{H}\}\text{-}^{31}\text{P}\{-^1\text{H}\}$  COSY spectrum indicates the two  $^{31}\text{P}$  signals at  $\delta \approx -46.1$  and 1.8 are coupled and are in the integral ratio 1 : 1. The former signal,  $\delta -46.1$ , is close to that of free dmpe, while the latter is typical of a bound  $\text{PMe}_2\text{Ph}$   $^{31}\text{P}\{-^1\text{H}\}$  signal. A careful examination of the signals at  $\delta -46.1$  and 1.8 reveals that both are a part of a complex spin system. For the purpose of simulation we assumed an AA'A''A'''BB'B''B''' spin system with the observed and simulated spectra being shown in Fig. 8. It is

also worthy of mention that the color of the solution is dark blue, typical of a  $\text{MoCl}_4\text{L}_4$  compound, where L =  $\text{PMe}_3$ ,  $\text{PET}_3$ ,  $\text{PMe}_2\text{Ph}$  or  $\text{PBU}^n$ . Although there is to our knowledge no known compound of the type  $\text{M}_2\text{Cl}_4(\text{dmpe-}P)_4$  there are mononuclear complexes containing dmpe-*P* and related diphosphine ligands.<sup>14</sup> We thus rest our case for the existence of the compound  $\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4$  in solution. The data pertaining to the kinetics of its formation will be discussed along with related data for other studies of reaction (2).

Reaction (2) was also studied for L' = pyridine (or  $[\text{D}_5]\text{pyridine}$ ). For  $\text{Mo}_2\text{Cl}_4\text{L}_4$ , where L =  $\text{PET}_3$  or  $\text{PMe}_2\text{Ph}$ , we observed some pyridine for L substitution. Indeed, from variable temperature studies we were able to monitor the equilibria (3a) and (3b). A  $\text{Mo}_2\text{Cl}_4\text{L}(\text{py})_3$  complex could be detected but only in

very low concentrations. [The compounds  $\text{Mo}_2\text{X}_4(\text{py})_4$  are known for X = Cl or Br.<sup>15</sup>] We were able to obtain the thermodynamic parameters  $\Delta H^\circ$  and  $\Delta S^\circ$  from Arrhenius plots. For L =  $\text{PET}_3$ ,  $\Delta H^\circ = 5.2(4) \text{ kcal mol}^{-1}$  and  $\Delta S^\circ = 11(1) \text{ cal K}^{-1} \text{ mol}^{-1}$  and for L =  $\text{PMe}_2\text{Ph}$ ,  $\Delta H^\circ = 5.3(1) \text{ kcal mol}^{-1}$  and  $\Delta S^\circ = 6(4) \text{ cal K}^{-1} \text{ mol}^{-1}$ , which, of course, indicates that (i) the Mo-PR<sub>3</sub> bond is thermodynamically favored over Mo-py and (ii) that  $\text{PMe}_2\text{Ph}$  is slightly favored relative to  $\text{PET}_3$ . The latter could be understandable in terms of steric factors, as judged by Tolman's cone angles.<sup>16</sup> It should also be noted that the compound  $\text{Mo}_2\text{Cl}_4(\text{py})_4$  is known.<sup>15</sup> Finally we note that in neat  $[\text{D}_5]\text{pyridine}$  even  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$  shows evidence of the equilibrium (3a) at room temperature. The signal for the free  $\text{PMe}_3$  is slightly broadened, indicative of the reversible nature of (3a) on the NMR time-scale.

**Table 2** Activation parameters for the reactions  $M_2Cl_4L_4 + L' \rightarrow M_2Cl_4L_3L' + L$

### Kinetics of the disappearance of $M_2Cl_4L_4$ in reaction (2)

The reactions were monitored by  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectroscopy for three half-lives with 15 to 30 equivalents of  $L'$ . The rates of reaction showed no dependence on  $[L']$ . The rate of disappearance of  $M_2Cl_4L_4$  obeyed first-order kinetics. A summary of rate data is presented in Table 1.

The first and most apparent trend is that  $k_{\text{obs}}(\text{Mo}) > k_{\text{obs}}(\text{W})$ . This is consistent with the view that bond breaking is important in the rate-determining step as it is well recognized that metal-ligand bonds to third-row transition elements are stronger than those to second-row elements. [In our previous studies of the binding of Lewis bases such as  $\text{PBU}_3$  or  $\text{CN}^-$  to  $M_2(\text{OR})_6$  compounds the difference in M-L bond energies were small, *ca.* 3 kcal mol<sup>-1</sup>, and in the order  $W-L > Mo-L$ .]<sup>17</sup> In the present study this is seen in the magnitude of the  $\Delta H^\ddagger$  values listed in Table 2. Consistently we observe that  $\Delta H^\ddagger(\text{W}) > \Delta H^\ddagger(\text{Mo})$  by *ca.* 3 kcal mol<sup>-1</sup>. Comparable rates of substitution are seen for  $M = W$  with a *ca.* 40 °C higher temperature than for  $M = Mo$  for a given ligand set. The second important factor that is evident from an inspection of the rate data in Table 1 is the influence of the leaving group. For example, the less bulky  $L = \text{PMe}_2\text{Ph}$  is replaced more slowly than  $L = \text{PEt}_3$ .

Both of the above findings are consistent with the work of Andersen and co-workers.<sup>10</sup> However, the third observation that can be seen from the data in Table 1 is that  $k_{\text{obs}}$  is influenced by the entering ligand  $L'$ . This is masked in some instances by the fact that there are isokinetic temperatures. For example, at -5 °C  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  reacts at essentially the same rate with  $\text{PMe}_3$  as it does with  $\text{PMe}_2\text{Ph}$  and *dmpe*. However, at +15 °C the rates differ quite markedly, certainly well outside the limits of experimental error. This difference of rate dependence with temperature owes its origin to differing entropies of activation. One should also note that a similar difference is seen in substitution reactions of  $W_2Cl_4L_4$  complexes. This provides the first piece of evidence that substitution is not proceeding *via* a **simple** dissociative mechanism and that reactive  $[M_2Cl_4L_3]^\ddagger$  species, solvated by  $[^2\text{H}_8]\text{toluene}$ , are not present in solution.

Having established the rates of substitution for  $\text{Mo}_2\text{Cl}_4L_4$  complexes we are able to test for the hypothetical dissociative process as proposed by Andersen, by carrying out reactions involving the mixing of  $\text{Mo}_2\text{Cl}_4L_4$  and  $\text{Mo}_2\text{Cl}_4L'_4$ . So for example at +50 °C in  $[^2\text{H}_8]\text{toluene}$  a dissociative mechanism would lead to ligand scrambling and the formation of  $\text{Mo}_2\text{Cl}_4L_{4-n}L'_n$  complexes, readily detectable by  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectroscopy. When  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_4$  and  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  were heated in  $[^2\text{H}_8]\text{toluene}$  at 45 °C for 15 h the scrambled products  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_{4-n}(\text{PEt}_3)_n$  were seen to be formed. This might at first be viewed as evidence for the D mechanism. However, given that the  $\text{Mo}-\text{PMe}_2\text{Ph}$  and  $\text{Mo}-\text{PEt}_3$  bonds have a very similar energy [as seen in the  $\Delta H^\ddagger$  values determined for reaction (3a)], any free tertiary phosphine, which could arise by decomposition, could catalyse the scrambling of the ligands. However, in the reactions between  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  and  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$ , and,  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_4$  and  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$ , no such scrambling was observed at +50 °C, in  $[^2\text{H}_8]\text{toluene}$  over 15 h.

**Fig. 9** Difference  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectra of spin magnetization transfer experiments involving  $\text{Mo}_2\text{Cl}_4L_4$  and  $L$ , where  $L = \text{PEt}_3$  (top) and  $\text{PMe}_3$  (bottom) at 25 and 50 °C, shown left and right, respectively

In these reactions the  $\text{Mo}_2\text{Cl}_4L_4$  complexes, where  $L = \text{PEt}_3$  or  $\text{PMe}_2\text{Ph}$ , would act as 'traps' for any free  $\text{PMe}_3$ . The ligand scrambling reaction would thus be quenched by the formation of  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_3(\text{PMe}_3)$  and the liberation of an equivalent of  $\text{PEt}_3$  which, as we have stated earlier, is not capable of displacing a  $\text{Mo}-\text{PMe}_3$  bond in  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$ . The trace amount of  $\text{PMe}_3$  that might have been present in such a solution mixture would go unnoticed in that the concentration of  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_3(\text{PMe}_3)$  would be very low.

Given that in  $[^2\text{H}_5]\text{pyridine}$   $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$  enters into the equilibrium (3a), we carried out the reaction between  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  and  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$  in this solvent. Upon mixing we observed scrambling. At room temperature (25 °C) we observed  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$ , free  $\text{PEt}_3$ ,  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)(\text{PMe}_3)(\text{py})_2$  and  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_3(\text{py})$  and  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_2(\text{py})_2$ . Upon heating to 60 °C for 15 h and returning the sample to 25 °C we observed free  $\text{PEt}_3$ ,  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$ ,  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)(\text{PMe}_3)(\text{py})_2$ ,  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_2(\text{PEt}_3)(\text{py})$ ,  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_3(\text{py})$  and  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_2(\text{py})_2$ . For the compound  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_2(\text{PEt}_3)(\text{py})$  the two  $\text{PMe}_3$  ligands are on adjacent metal atoms as determined by  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectroscopy. From the latter we conclude that pyridine facilitates ligand scrambling by what may be viewed as a solvent-assisted dissociative process for the  $\text{Mo}-\text{PR}_3$  ligands. The lack of any detectable free  $\text{PMe}_3$  in the above reaction mixture reflects its higher affinity for the  $\text{Mo}_2$  center relative to  $\text{PEt}_3$ .

Since pyridine is itself a good nucleophile one might wonder what is meant by the term solvent-assisted dissociation of the  $\text{Mo}-\text{PR}_3$  bonds. Also one might speculate that a different reaction pathway is possible in this solvent. We thus returned to investigate further the reaction (2) carried out in  $[^2\text{H}_8]\text{toluene}$  where  $L = L'$ , *i.e.* the degenerate replacement of one tertiary phosphine by itself.

### Spin magnetization transfer experiments

The reactions involving  $\text{Mo}_2\text{Cl}_4L_4$  with an excess of  $L$  in  $[^2\text{H}_8]\text{toluene}$  were studied as a function of temperature for both  $L = \text{PEt}_3$  and  $\text{PMe}_3$ . Irradiation at the frequency of the free phosphine and inspection of the co-ordinated  $L$  signal by difference spectroscopy reveals at 25 °C a positive enhancement of it as shown in Fig. 9. This is not consistent with  $L$  exchange since this would give rise to a negative difference spectrum. The only explanation for a positive difference spectrum arises from nuclear Overhauser enhancement (NOE)<sup>18</sup> wherein a significant concentration of free  $L$  is within the co-ordination sphere of the  $\text{Mo}_2\text{Cl}_4L_4$  complex. This is actually to be expected since all  $M_2^{4+}$  quadruply bonded complexes have a weak affinity to bind ligands in the axial position, *i.e.* along the  $M-M$  axis.<sup>1</sup> Thus, we ascribe the positive difference spectrum to the equilibrium (4). The equilibrium (4) must be kinetically labile as

we see no direct evidence for  $\text{Mo}_2\text{Cl}_4\text{L}_4\text{L}_n$  species where  $n = 1$  or 2.

Upon heating to  $+50^\circ\text{C}$  there are unequivocal negative difference spectra (see Fig. 9) indicative of significant  $^{31}\text{P}$  site exchange between the free and the co-ordinated ligands on the NMR time-scale. This is a particularly important observation for  $\text{L} = \text{PMe}_3$  since this tertiary phosphine is otherwise inert to substitution by other  $\text{R}_3\text{P}$  ligands. Also in the lack of reactivity observed between  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  and  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$  at  $50^\circ\text{C}$  in  $[\text{H}_8]\text{toluene}$  it could be argued that  $\text{Mo}-\text{PMe}_3$  bond dissociation does not occur unless pyridine is present.

## Conclusion

While much of the present work corroborates the findings of Andersen and co-workers,<sup>10</sup> we do see certain differences. For reaction (2) the importance of bond breaking is clearly evident from the relative rates of reactions for related molybdenum and tungsten complexes. Also the notion that substitution proceeds to release steric strain at the dimetal center finds support in that  $\text{PMe}_3$  is resistant to substitution by  $\text{PEt}_3$  and  $\text{PMe}_2\text{Ph}$ . However, we have found that  $\text{PMePh}_2$  will displace one ligand to form  $\text{Mo}_2\text{Cl}_4\text{L}_3(\text{PMePh}_2)$  where  $\text{L} = \text{PEt}_3$ ,  $\text{PMe}_2\text{Ph}$  or  $\text{PBU}^n_3$ . Here a more bulky phosphine with a Tolman cone angle of  $136^\circ$  replaces one with an angle of  $132^\circ$  ( $\text{L} = \text{PEt}_3$  and  $\text{PBU}^n_3$ ) and  $122^\circ$  ( $\text{L} = \text{PMe}_2\text{Ph}$ ).<sup>16</sup> The kinetics of this last reaction clearly indicates the existence of the equilibrium (5) ( $\text{L} = \text{PEt}_3$ ,  $\text{PBU}^n_3$  or  $\text{PMe}_2\text{Ph}$ ) (see Experimental section).

Evidence against a simple dissociative mechanism involving the equilibrium (6) comes from a number of observations. (1) In

our studies of the rates of substitution, equation (2), we see that there is an influence of the entering ligand  $\text{L}'$ . This manifests itself principally in the differing entropies of activation. (2) The kinetic lability of  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$  to enter into  $\text{PMe}_3$  scrambling in  $[\text{H}_8]\text{toluene}$  in the presence of free  $\text{PMe}_3$  (as evidenced by spin magnetization transfer) is in marked contrast to its inertness to phosphine scrambling in the presence of  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  in toluene. (3) The pyridine-promoted phosphine scrambling is understandable in terms of the pyridine-assisted dissociation of  $\text{PR}_3$  ligands, equations (3a) and (3b). (4) The reaction with *dmpe*, which proceeds from  $\text{Mo}_2\text{Cl}_4\text{L}_4$  directly to  $\text{Mo}_2\text{Cl}_4(\text{dmpe}-P)_4$ , indicates that once one of the chelating phosphine bonds accesses an equatorial site by displacement of  $\text{L}$  then the complex is labilized toward dissociation of additional  $\text{L}$ . This most readily can be accounted for by an equilibrium of type (4) since the unco-ordinated  $\text{PMe}_2$  group can rapidly and reversibly occupy the axial site. Thus the position of the equilibrium (4) is effectively displaced to the right.

We therefore conclude that the phosphine exchange occurs by an interchange dissociative mechanism,  $\text{I}_d$ , wherein the entering ligand effectively moves from an axial site to an equatorial position as the latter  $\text{M}-\text{PR}_3$  bond breaks. [In studies of the  $\text{H}_2\text{O}$  exchange in  $\text{Mo}_2^{4+}$  (aq) Sykes and co-workers<sup>19</sup> compared the relative lability of  $\text{H}_2\text{O}$  exchange in the axial position *versus* that in the equatorial position to that seen for  $\text{V}^{\text{V}}\text{-oxo}$  (aq) ion.]

Bearing in mind 'to never trust in science to the principle of exclusion'<sup>11</sup> we would finally like to suggest that substitution reactions at  $\text{M}_2^{4+}$  ( $\text{M} \equiv \text{M}$ ) centers are in general unlikely to proceed *via* a limiting dissociative reaction pathway since these complexes are unsaturated. The situation is somewhat akin to substitution at square-planar platinum(II).<sup>20</sup> However, the relative importance of bond breaking and bond forming will surely be greatly influenced by the nature of the entering and leaving ligands, the solvent and overall charge on the complex. The

greater kinetic lability of  $\text{Mo}_2\text{Me}_4\text{L}_4$  compared with  $\text{Mo}_2\text{Cl}_2\text{L}_4$  can be understood in terms of the effective charge at the  $\text{Mo}_2$  center as the electron donating properties of  $\text{Me}$  are greater than those of  $\text{Cl}$ .

## Experimental

All manipulations were carried out using standard Schlenk-line and glove-box techniques under an atmosphere of argon or nitrogen. The deuteriated solvents,  $[\text{H}_8]\text{toluene}$  and  $[\text{H}_5]\text{pyridine}$ , were freeze-pump-thaw degassed and stored under nitrogen over molecular sieves (4 Å) prior to use. Standard solutions of  $\text{PMe}_2\text{Ph}$ ,  $\text{PMePh}_2$ , *dmpe* and pyridine were prepared using  $[\text{H}_8]\text{toluene}$  and stored under argon. Pyridine was dried over sodium, distilled, degassed and stored under nitrogen over molecular sieves (4 Å) prior to use. The  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectra were recorded on a Varian I400 spectrometer at 166.9 MHz and referenced externally relative to 85%  $\text{H}_3\text{PO}_4$ . Simulations of such spectra were performed using GNMR V3.6 software. The chemical shifts and coupling constants were optimized by assignment iteration, a least-squares iteration procedure that produces a fit between the observed experimental spectra and calculated peak positions. The dimolybdenum compounds  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_4$ ,  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  and  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$  were prepared from  $\text{Mo}_2(\text{O}_2\text{CMe})_4$  by the general procedure described.<sup>21</sup> The ditungsten complexes  $\text{W}_2\text{Cl}_4(\text{PEt}_3)_4$ ,  $\text{W}_2\text{Cl}_4(\text{PBU}^n_3)_4$  and  $\text{W}_2\text{Cl}_4(\text{PMe}_3)_4$  were prepared from the reduction of  $\text{WCl}_4$  by the general procedure described.<sup>22</sup> The phosphine ligands  $\text{PMe}_3$ ,  $\text{PEt}_3$ ,  $\text{PBU}^n_3$ ,  $\text{PMe}_2\text{Ph}$  and  $\text{PMePh}_2$  were purchased from Aldrich and the diphosphine ligand *dmpe* from Strem.

### General sample preparation for measurement of kinetics

For all the rate determinations the disappearance of the  $\text{Mo}_2\text{Cl}_4\text{L}_4$  complex was monitored over at least three half-lives under pseudo-first-order conditions. Linear plots of  $\ln k$  *versus*  $1/T$  were obtained thus indicating that the reaction was first order in  $[\text{Mo}_2\text{Cl}_4\text{L}_4]$ . This was true for all cases except where  $\text{L}' = \text{PMePh}_2$ , where after approximately one half-life the plot levelled out and an equilibrium situation was obtained. Both before and after each experiment the temperature of the NMR machine was calibrated using neat methanol ( $<25^\circ\text{C}$ ) or neat ethylene glycol ( $>25^\circ\text{C}$ ), with an equilibration time of at least 15 min and the acquisition of at least three spectra. The temperature before and after each experiment did not vary by more than  $0.4^\circ\text{C}$ .

The samples were generally prepared using J. Young<sup>®</sup> NMR tubes in a helium glove-box. The  $\text{Mo}_2\text{Cl}_4\text{L}_4$  complex was weighed using an analytical balance accurate to 0.1 mg. The stock  $[\text{H}_8]\text{toluene}$  solutions of the phosphine ligands were then added *via* a microlitre syringe, except in the case of  $\text{PMe}_3$ , which was volatile enough to be transferred using a calibrated gas manifold. For  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  it was imperative that the samples were prepared and maintained at a low temperature (generally  $-78^\circ\text{C}$ ) prior to the measurements. This is easily achieved in the case of  $\text{PMe}_3$  which was condensed into a J. Young<sup>®</sup> NMR tube at  $-196^\circ\text{C}$ , however in the case of the other phosphine ligands the  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  complex must be weighed in the helium box and capped with a small rubber septum through which the phosphine  $[\text{H}_8]\text{toluene}$  solutions could be injected whilst keeping the NMR sample at  $-78^\circ\text{C}$ .

The pulse width and  $T_1$  of the  $^{31}\text{P}$  nuclei were determined by standard techniques as outlined in the Varian manual. A delay time ( $d_1$ ) of at least  $5T_1$  was then used during the acquisition of the  $^{31}\text{P}\{-^1\text{H}\}$  NMR data to ensure full relaxation and thus accurate measurement of the integration.

The standard deviations in the measurements of  $k_{\text{obs}}$  were determined by taking three measurements at one temperature, *e.g.* for  $\text{Mo}_2\text{Cl}_4(\text{PMe}_2\text{Ph})_4$  with 15 equivalents of  $\text{PMe}_3$  at  $40^\circ\text{C}$

<sup>a</sup> A through A'' represent the co-ordinated arm of the dmpe-P and B through B'' the dangling arm. The compound  $\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4$  is a complex spin system, AA'A''A'''BB'B''B''', which was simulated using GNMR V3.6. It was assumed that there was no coupling between B, B', B'' and B''', i.e. between the 'dangling' phosphine ligands. <sup>b</sup> The leaning observed for the two sets of doublet of triplets for the complex is due to second-order effects which were simulated using GNMR V3.6. <sup>c</sup> The  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectrum has complicated tungsten satellites which can be simulated using GNMR V3.6. This is clearly evident in the starting material  $\text{W}_2\text{Cl}_4(\text{PEt}_3)_4$ , which unlike its molybdenum analogue has complex satellites as  $^{183}\text{W}$  has 14.3% natural abundance, e.g.  $^1J(^{183}\text{WP}) = 238$ ,  $^2J(^{183}\text{WP}) = 51$ ,  $^3J(\text{PP}) = 29$  Hz, with zero coupling to the spin-inactive tungsten and no  $^2J(\text{PP})$  coupling as the *trans* phosphine ligands are magnetically equivalent due to symmetry. <sup>d</sup> Upon the addition of neat [ $^2\text{H}_5$ ]pyridine to  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_4$  only a small amount of  $\text{Mo}_2\text{Cl}_4(\text{PMe}_3)_3(\text{py})$  and free  $\text{PMe}_3$  were observed. Heating the sample to 60 °C did result in a further small liberation of  $\text{PMe}_3$  but the concentrations were so small that equilibrium constant measurements were not possible.

$k_{\text{obs}} = 4.91 \times 10^{-5}$ ,  $4.96 \times 10^{-5}$ ,  $4.96 \times 10^{-5} \text{ s}^{-1}$ , and then calculating the standard deviation by standard mathematical techniques. In this case the standard deviation was  $0.03 \times 10^{-5} \text{ s}^{-1}$ , thus the value is reported as  $4.94(3) \times 10^{-5} \text{ s}^{-1}$ . Errors in the fit of the Eyring plots were determined using non-linear regression analysis performed using SIGMA PLOT 3.0.

**Reaction of  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  with L' ( $\text{PMe}_3$ ,  $\text{PMe}_2\text{Ph}$  or dmpe).** The sample temperature was maintained at -78 °C prior to the experiment. The rate of disappearance of  $\text{Mo}_2\text{Cl}_4(\text{PEt}_3)_4$  was monitored in the temperature range -5 to 15 °C at 5 °C intervals *via*  $^{31}\text{P}\{-^1\text{H}\}$  NMR spectroscopy. The NMR data are given in Table 3.

The compound  $[\text{Mo}_2\text{Cl}_4(\text{dmpe-}P)_4]$  is a complex spin system, AA'A''A'''BB'B''B''', which was simulated using GNMR V3.6. It was assumed that there was no coupling between B, B', B'' and B''', i.e. between the 'dangling' phosphine  $^{31}\text{P}$  nuclei.

**Reaction of  $\text{M}_2\text{Cl}_4\text{L}_4$  with  $\text{PMe}_3$  ( $\text{M} = \text{Mo}$ ,  $\text{L} = \text{PMe}_2\text{Ph}$ ;  $\text{M} = \text{W}$ ,  $\text{L} = \text{PEt}_3$  or  $\text{PBu}_3$ ).** A J. Young<sup>®</sup> NMR tube was charged with  $\text{M}_2\text{Cl}_4\text{L}_4$  (0.0086 mmol) and [ $^2\text{H}_8$ ]toluene (600  $\mu\text{l}$ ). The blue solution was then cooled to -196 °C using liquid nitrogen and the NMR tube evacuated. Trimethylphosphine (0.14 mmol) was then condensed into the NMR tube *via* a calibrated gas-transfer manifold. The reaction was then allowed to attain room temperature and the rate of disappearance of

[Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub>] was monitored *via* <sup>31</sup>P-{<sup>1</sup>H} NMR spectroscopy in the temperature range 35 to 60 °C for M = W and -5 to 15 °C for M = Mo at 5 °C intervals. The NMR data are given in Table 3.

The leaning observed for the two sets of doublet of triplets for the complex Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>2</sub>Ph)<sub>3</sub>(PMe<sub>3</sub>) is due to second-order effects which were simulated using GNMV3.6.

**Reaction of Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> with dmpe, where L = PMe<sub>2</sub>Ph or PBu<sup>n</sup>.** A NMR tube was charged with Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> (0.017 mmol) and dmpe (600 μl, 0.22 M, 0.17 mmol). The NMR machine was warmed to 50 °C and calibrated with neat ethylene glycol. After the desired temperature was attained the sample was inserted and the reaction followed by <sup>31</sup>P-{<sup>1</sup>H} NMR spectroscopy (data in Table 3).

Note that not all the Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> complex was consumed; even at 60 °C only a small amount of Mo<sub>2</sub>Cl<sub>4</sub>(dmpe-P)<sub>4</sub> and PMe<sub>3</sub> were formed. Further, prolonged heating at 60 °C resulted in the cleavage of the Mo≡Mo quadruple bond as the color changes from deep blue to pale red and the only peaks identified in the <sup>31</sup>P-{<sup>1</sup>H} NMR spectrum were due to free PMe<sub>3</sub> and free dmpe.

**Reaction of Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> with L' (PMe<sub>2</sub>Ph, PMePh<sub>2</sub> or PEt<sub>3</sub>).** A J. Young<sup>®</sup> NMR tube charged with Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> (4.5 mg, 0.007 mmol) and L' (772 μl of 0.22 M, 0.17 mmol) was heated at 50 °C for 15 h with no observable change detected in the <sup>31</sup>P-{<sup>1</sup>H} NMR spectrum (data in Table 3).

**Reaction of W<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> with L', where L = PEt<sub>3</sub> or PBu<sup>n</sup> and L' = PMe<sub>2</sub>Ph or PMePh<sub>2</sub>.** A J. Young<sup>®</sup> NMR tube was charged with W<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> (0.0107 mmol) and L' (600 μl, 0.22 M, 0.17 mmol) to afford a green solution. The disappearance of W<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> was monitored over at least three half-lives by <sup>31</sup>P-{<sup>1</sup>H} NMR spectroscopy in the temperature range 35 to 60 °C at 5 °C intervals, unless otherwise stated.

The <sup>31</sup>P-{<sup>1</sup>H} NMR spectra of these tungsten complexes have complicated tungsten satellites which can be simulated using GNMV3.6. This is clearly evident for the starting material W<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>4</sub>, which unlike its molybdenum analogue has complex satellites as <sup>183</sup>W has 14.3% natural abundance.

**Reaction of Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> with pyridine, where L = PEt<sub>3</sub>, PMe<sub>2</sub>Ph or PMe<sub>3</sub>.** Upon addition of neat [<sup>2</sup>H<sub>5</sub>]pyridine (600 μl) to Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> (0.037 mmol) pyridine/phosphine exchange was observed to varying degrees depending upon L and the temperature. The equilibria, where L = PEt<sub>3</sub> or PMe<sub>2</sub>Ph, were examined using a 2.36 M solution of pyridine in [<sup>2</sup>H<sub>8</sub>]toluene (600 μl, 0.471 mmol) by <sup>31</sup>P-{<sup>1</sup>H} NMR spectroscopy over the temperature range 20 to 80 °C at 10 °C intervals. The sample was allowed to equilibrate at each temperature for at least 25 min.

A reversible equilibrium was found to be in effect and K<sub>1</sub> values were calculated at various temperatures and from an Arrhenius plot the ΔH° and ΔS° of the reaction could be calculated: K<sub>1</sub> = [Mo<sub>2</sub>Cl<sub>4</sub>L<sub>3</sub>(py)]/[L]/[Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub>][py]; for L = PEt<sub>3</sub>, ΔH<sub>1</sub>° = 5.3(4) kcal mol<sup>-1</sup>, ΔS<sub>1</sub>° = 11(1) cal K<sup>-1</sup> mol<sup>-1</sup>; for L = PMe<sub>2</sub>Ph, ΔH<sub>1</sub>° = 5.2(4) kcal mol<sup>-1</sup>, ΔS<sub>1</sub>° = 11(1) cal K<sup>-1</sup> mol<sup>-1</sup>. The NMR data are given in Table 3.

Upon the addition of neat [<sup>2</sup>H<sub>5</sub>]pyridine to Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> only a small amount of Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>3</sub>(py) and free PMe<sub>3</sub> were observed. Heating the sample to 60 °C did result in a further small liberation of PMe<sub>3</sub> but the concentrations were so small that equilibrium constant measurements were not possible.

**Reaction of Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>4</sub> with Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> in pyridine.** A J. Young<sup>®</sup> NMR tube was charged with Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>4</sub> (5.4 mg, 0.0067 mmol), Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> (6.0 mg, 0.0094 mmol) and [<sup>2</sup>H<sub>5</sub>]pyridine (600 μl). From <sup>31</sup>P-{<sup>1</sup>H} NMR spectroscopy it was

determined that PEt<sub>3</sub>, Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub>, Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>4</sub>, Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>3</sub>(py), Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)(PMe<sub>3</sub>)(py)<sub>2</sub> and Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>2</sub>(py)<sub>2</sub> were formed at room temperature. The reaction was then monitored by <sup>31</sup>P-{<sup>1</sup>H} NMR spectroscopy at 25 °C and no change was observed over 48 h. The sample was then heated at 60 °C for 24 h, after which time the new products Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)(PMe<sub>3</sub>)<sub>2</sub>(py), Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>2</sub>(PMe<sub>3</sub>)(py) and Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>2</sub>(py)<sub>2</sub> could be identified in the <sup>31</sup>P-{<sup>1</sup>H} NMR spectrum.

**Reaction of Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>2</sub>Ph)<sub>4</sub> and Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> in pyridine.** A J. Young<sup>®</sup> NMR tube was charged with Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>2</sub>Ph)<sub>4</sub> (8.8 mg, 0.01 mmol), Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> (6.0 mg, 0.009 mmol) and [<sup>2</sup>H<sub>5</sub>]pyridine (600 μl). Upon mixing, PMe<sub>2</sub>Ph, Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub>, Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>2</sub>Ph)<sub>4</sub> and Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>2</sub>Ph)<sub>3</sub>(py) could be identified in the <sup>31</sup>P-{<sup>1</sup>H} NMR spectrum at room temperature. After heating at 55 °C for 24 h Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>2</sub>Ph)<sub>2</sub>(PMe<sub>3</sub>)(py) could also be identified in the <sup>31</sup>P-{<sup>1</sup>H} NMR spectrum.

**Reaction of Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>2</sub>Ph)<sub>4</sub> and Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>4</sub> in toluene.** A J. Young<sup>®</sup> NMR tube charged with Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>2</sub>Ph)<sub>4</sub> (6.5 mg, 0.007 mmol), Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>4</sub> (5.8 mg, 0.08 mmol) and [<sup>2</sup>H<sub>8</sub>]toluene (600 μl) was heated at 40 °C for 24 h, after which time Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub>, Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>2</sub>Ph)<sub>4</sub>, Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>3</sub>(PMe<sub>2</sub>Ph), Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>2</sub>(PMe<sub>2</sub>Ph)<sub>2</sub> (AA'BB'), Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)<sub>2</sub>(PMe<sub>2</sub>Ph)<sub>2</sub> (A<sub>2</sub>B<sub>2</sub>) and Mo<sub>2</sub>Cl<sub>4</sub>(PEt<sub>3</sub>)(PMe<sub>2</sub>Ph)<sub>3</sub> were determined in the <sup>31</sup>P-{<sup>1</sup>H} NMR spectrum.

**Reaction of Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> and Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> in toluene, where L = PEt<sub>3</sub> or PMe<sub>2</sub>Ph.** A J. Young<sup>®</sup> NMR tube charged with Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> (0.0107 mmol), Mo<sub>2</sub>Cl<sub>4</sub>(PMe<sub>3</sub>)<sub>4</sub> and [<sup>2</sup>H<sub>8</sub>]toluene (600 μl) was heated at 50 °C for 15 h with no observable change detected in the <sup>31</sup>P-{<sup>1</sup>H} NMR spectrum.

**Spin transfer magnetization <sup>31</sup>P-{<sup>1</sup>H} NMR experiment with Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> and L (PMe<sub>3</sub> or PEt<sub>3</sub>).** A J. Young<sup>®</sup> NMR tube was charged with Mo<sub>2</sub>Cl<sub>4</sub>L<sub>4</sub> (0.012 mmol), L (0.05 mmol) and [<sup>2</sup>H<sub>8</sub>]toluene (600 μl). The sample was then irradiated at the frequency corresponding to the free phosphine at various temperatures (25 to 60 °C). The corresponding blank spectrum in which neither peak was irradiated was also acquired. From the subtraction of the blank from the irradiated spectrum a difference NOE spectrum was obtained.
