# Synthesis, structure and redox behaviour of facial $\left[\mathrm{Re}^{\mathrm{III}} \mathbf{L}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ and its stereoretentive conversion to $\left[\operatorname{Re}^{\mathrm{IV}} \mathbf{L}^{\prime}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ via metal promoted aldimine $\longrightarrow$ amide oxidation ( $\mathbf{L}=$ pyridine-2-aldimine; $\mathbf{L}^{\prime}=$ pyridine-2-carboxamide)

Received 11th August 1998, Accepted 29th October 1998

The reaction of mer- $\left[\mathrm{Re}{ }^{\mathrm{III}} \mathrm{L}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right] \mathbf{2}$ with $\mathrm{PPh}_{3}$ in benzene has afforded bluish violet fac- $\left[\mathrm{Re}^{\mathrm{III}} \mathrm{L}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] \mathbf{1}$, where $L$ is the Schiff base of pyridine-2-carbaldehyde and the substituted aniline $p-\mathrm{XC}_{6} \mathrm{H}_{4} \mathrm{NH}_{2}(\mathrm{X}=\mathrm{H}, \mathrm{Me}$, OMe or $\mathrm{Cl})$. Geometrical preferences are rationalized in terms of the electronic nature of the ligands $\mathrm{OPPh}_{3}$ ( $\sigma$ - and $\pi$-donor), $\mathrm{PPh}_{3}$ ( $\sigma$-donor and $\pi$-acceptor) and L ( $\sigma$-donor and $\pi$-acceptor). The cyclic voltammetric $E_{1 / 2}$ values of $\mathbf{1}$ lie near $0.6 \mathrm{~V}\left(\mathrm{Re}^{\mathrm{IV}}-\mathrm{Re}^{\mathrm{II}}\right)$ and $-0.6 \mathrm{~V}\left(\mathrm{Re}^{\mathrm{II}}-\mathrm{Re}^{\mathrm{II}}\right)$. Electrooxidation of $\mathbf{1}$ at $1.0 \mathrm{~V} v s$. SCE in wet acetonitrile affords yellow fac- $\left[\operatorname{Re}^{\mathrm{IV}} \mathrm{L}^{\prime}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] \mathbf{3}$ which is also obtainable via oxidation by dilute nitric acid ( $\mathrm{L}^{\prime}$ is a monoanionic pyridine-2carboxamide). Complex 3 displays $\mathrm{Re}^{\mathrm{IV}}-\mathrm{Re}^{\mathrm{III}}$ and $\mathrm{Re}^{\mathrm{V}}-\mathrm{Re}^{\mathrm{IV}}$ couples near -0.2 V and 1.4 V respectively reflecting superior stabilization of the rhenium(Iv) state by the amide ligand. The X-ray structures of two representative complexes of type $\mathbf{1}$ and $\mathbf{3}$ have revealed the presence of severely distorted and facially configured $\mathrm{RePN}_{2} \mathrm{Cl}_{3}$ coordination spheres. The average $\mathrm{Re}-\mathrm{Cl}$ distance is lower by $0.06 \AA$ in $\mathbf{3}$ due to contraction of the metal radius upon oxidation. The Re-P length is however larger by $0.1 \AA$ in $\mathbf{3}$ signifying a weakening of Re-P back-bonding.

The rhenium chemistry of Schiff bases of pyridine-2carbaldehyde is under scrutiny in this laboratory. Facile oxygen-atom-transfer, metal-mediated ligand oxidation and stabilization of unusual rhenium moieties are among the notable features that have so far been documented. ${ }^{1-6}$ In this work we disclose a spontaneous geometrical transformation associated with ligand substitution. The reaction has afforded a family of pyridine-2-aldimine chelates of trivalent rhenium incorporating phosphine coordination. The species are redox active and undergo facile aldimine $\longrightarrow$ amide oxidation. The structure and properties of the present complexes and their oxidized derivatives are described.

## Results and discussion

Synthesis of fac-[ $\left.\mathrm{ReL}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] 1$
Four pyridine-2-aldimine ligands ( $\mathrm{L}^{1}-\mathrm{L}^{4}$; general abbreviation is L ), differing in the X substituent have been utilized. The complexes have facial geometry (see below) and are formed upon reacting the meridional phosphine oxide complexes of type $\left[\operatorname{ReL}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right]$ 2, ${ }^{1-3}$ with $\mathrm{PPh}_{3}$, in boiling benzene,

1a $\left[\operatorname{ReL}^{1}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right](\mathrm{X}=\mathrm{H})$
1b $\left[\mathrm{ReL}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right](\mathrm{X}=\mathrm{Me})$
1c $\left[\operatorname{ReL}{ }^{3}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right](\mathrm{X}=\mathrm{OMe})$
1d $\left[\operatorname{ReL}^{4}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right](\mathrm{X}=\mathrm{Cl})$

$2\left[\mathrm{ReL}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right]$
equation (1). The reaction of mer- $\left[\mathrm{ReOCl}_{3}\left(\mathrm{PPh}_{3}\right)_{2}\right]$ with L also furnishes 1 , equation (2), but in poorer yield.

$$
\begin{align*}
\text { mer }-\left[\operatorname{ReL}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right]+ & \mathrm{PPh}_{3} \longrightarrow \\
\text { fac- }\left[\mathrm{ReL}^{\longrightarrow}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]+ & \mathrm{OPPh}_{3} \tag{1}
\end{align*}
$$

Selected spectral and magnetic characterization data for the complexes are listed in Tables 1 and 2. The magnetic moments $\left(\approx 2 \mu_{\mathrm{B}}\right.$, Table 1) are lower than the spin-only value for the $\mathrm{t}_{2 \mathrm{~g}}{ }^{4}$ (assuming idealised octahedral geometry) configuration which is not unusual for trivalent rhenium. ${ }^{7}$ The paramagnetically shifted ${ }^{1} \mathrm{H}$ NMR signals of $\mathbf{1}$ have been assigned (Table 2) on the basis of signal intensity, spin-spin structure and previous work. ${ }^{8-10}$ A selected portion of the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{1 b}$ is displayed in Fig. 1.

## Structure

The X-ray structure of $f a c$ - $\left[\operatorname{ReL}^{1}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ 1a has been determined. A molecular view is shown in Fig. 2 and selected bond parameters are listed in Table 3. The aldimine and phosphine ligands are facially disposed and so are the chloride ligands, forming a severely distorted octahedral $\mathrm{RePN}_{2} \mathrm{Cl}_{3}$ coordination sphere. The chelate ring along with the pyridine ring and $\mathrm{Cl}(2), \mathrm{Cl}(3)$ atoms constitute a good plane (mean deviation 0.05 $\AA$ ) to which the pendent phenyl ring makes a dihedral angle of $50.1^{\circ}$.

The X-ray structures of a few $\mathrm{Re}^{\text {III }}-\mathrm{PPh}_{3}$ complexes are known. ${ }^{8,11,12}$ Only one of these has the $\mathrm{ReCl}_{3}$ moiety but in a meridional configuration. ${ }^{8}$ To the best of our knowledge $\mathbf{1 a}$ is the first structurally characterized $\mathrm{PPh}_{3}$ complex having facial $\mathrm{ReCl}_{3}$ disposition. The Re- P distance, 2.463(2) $\AA$ in 1a is normal. ${ }^{8,12}$

Fig. 1 A part of the proton NMR spectrum of $f a c-\left[\operatorname{ReL}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] \mathbf{1 b}$ in $\mathrm{CDCl}_{3}$ solution; $o-\mathrm{H}, m$ - H and $p-\mathrm{H}$ refer respectively to ortho, meta and para protons of $\mathrm{PPh}_{3}$.

## Geometrical preference

The striking geometrical difference between $\mathbf{1}$ and $\mathbf{2}$ is believed to be of electronic origin. In $\mathbf{1}, \mathrm{PPh}_{3}$ is a $\pi$-accepting ligand, the acceptor orbital being a mixture of $3 \mathrm{~d}_{\pi}$ and $\mathrm{P}-\mathrm{C} \sigma^{*}$ components. ${ }^{13}$ The L ligand is also $\pi$-accepting due to the $\alpha$-diimine

function $(-\mathrm{N}=\mathrm{C}-\mathrm{C}=\mathrm{N}-)$., ${ }^{2,14}$ Trivalent rhenium is prone to backbonding. ${ }^{15}$ Assuming idealised octahedral geometry this bonding has $\mathrm{t}_{2 \mathrm{~g}}(\mathrm{Re}) \longrightarrow \pi(\mathrm{P})$ and $\mathrm{t}_{2 \mathrm{~g}}(\mathrm{Re}) \longrightarrow \pi^{*}(\mathrm{~L})$ components in 1. Back-bonding is maximized when the acceptor ligands are facially disposed so that competition between ligands for identical metal orbitals is minimal.

${ }^{a}$ Solvent, dichloromethane; scan rate, $50 \mathrm{mV} \mathrm{s}{ }^{-1} ; E_{\frac{1}{2}}=1 / 2\left(E_{\mathrm{pa}}+E_{\mathrm{pc}}\right)$ where $E_{\mathrm{pa}}$ and $E_{\mathrm{pc}}$ are anodic and cathodic peak potentials respectively; $\Delta E_{\mathrm{p}}=E_{\mathrm{pc}}-E_{\mathrm{pa}}$. Reference electrode, SCE. The concerned couples are $\mathbf{1}_{-1^{-}}\left(\operatorname{Re}^{\text {piII }}-\operatorname{Re}^{\text {pa }}\right), \mathbf{1}^{+}-\mathbf{1}\left(\operatorname{Re}^{\mathrm{IV}}-\operatorname{Re}^{\mathrm{III}}\right), \mathbf{3}-\mathbf{3}^{-}\left(\operatorname{Re}^{\mathrm{IV}}-\operatorname{Re}^{\mathrm{III}}\right), \mathbf{3}^{+}-\mathbf{3}\left(\operatorname{Re}^{\mathrm{V}}-\operatorname{Re}^{\mathrm{IV}}\right)$.

The meridional geometry is expected to be favoured by steric as well as electrostatic factors. In the case of $\mathbf{1}$ these advantages are more than offset by the superior back-bonding of the facial configuration. This does not apply to $\left[\mathrm{ReL}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right]$ since $\mathrm{OPPh}_{3}$ is purely a donor in both $\sigma$ and $\pi$ senses. Hence its geometry is logically meridional. It is instructive to compare the metal-ligand bond distances of $\mathbf{1 a}$ with those of mer$\left[\operatorname{ReL}^{2}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right] .{ }^{2}$ The average $\mathrm{Re}-\mathrm{Cl}$ length of two complexes are nearly equal ( $2.37-2.38 \AA$ ). However the Re-N lengths in 1a are ca. $0.06 \AA$ longer than those in the phosphine oxide complex where $L^{2}$ alone is available for back-bonding $\left[\mathrm{t}_{2 \mathrm{~g}}(\mathrm{Re}) \longrightarrow\right.$ $\left.\pi^{*}\left(\mathrm{~L}^{2}\right)\right]$.

The geometrical selectivity in $\mathbf{1}$ and $\mathbf{2}$ is strong and exclusive. In no case have isomers been observed. It is noteworthy that $\left[\operatorname{ReL}(\mathrm{O}) \mathrm{Cl}_{3}\right]^{3}$ and $\left[\operatorname{ReL}(\mathrm{NAr}) \mathrm{Cl}_{3}\right]^{5,6}$ are meridional, the O and NAr ligands being pure donors like $\mathrm{OPPh}_{3}$. Upon reacting 1 with aromatic amines $\left(\mathrm{ArNH}_{2}\right)$ in benzene solution in air, facile and quantitative transformation to mer- $\left[\mathrm{ReL}(\mathrm{NAr}) \mathrm{Cl}_{3}\right]$ occurs. This reaction ( $\mathrm{fac} \longrightarrow m e r$ ) represents a reversal of the geometrical change $(\mathrm{mer} \longrightarrow f a c)$ characterizing the reaction of equation (1).

## Metal redox: formation of $\left[\operatorname{ReL}^{\prime}\left(\mathbf{P P h}_{3}\right) \mathbf{C l}_{3}\right] \mathbf{3}$

The $\mathrm{fac}-\left[\mathrm{ReL}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ complexes are electroactive in dichloromethane solution displaying two quasi-reversible one-electron responses in the range -0.5 to 0.7 V vs. SCE. Reduction potential data are listed in Table 4. The responses are assigned to the $\operatorname{Re}^{\mathrm{IV}}-\operatorname{Re}^{\mathrm{III}}\left(E_{1 / 2} \approx 0.6 \mathrm{~V}\right)$ and $\mathrm{Re}^{\mathrm{II}}-\operatorname{Re}^{\mathrm{II}}\left(E_{1 / 2} \approx-0.6 \mathrm{~V}\right)$ couples. In 2 the $\mathrm{Re}^{\mathrm{IV}}-\mathrm{Re}^{\text {III }}$ couple occurs at ca. $0.3 \mathrm{~V}^{3}$ Thus the trivalent state of rhenium is more difficult to oxidize in $\mathbf{1}$ than in $\mathbf{2}$. This is consistent with the presence of phosphine back-bonding in $\mathbf{1}$.

The red oxidized complex $\left[\mathrm{Re}^{\mathrm{IV}} \mathrm{L}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]^{+} \mathbf{1}^{+}$can be generated in solution by coulometric oxidation of $\mathbf{1}$ in dry acetonitrile at 1.0 V . It reacts spontaneously with added water affording the amide complex $f a c-\left[\mathrm{Re}^{\mathrm{IV}} \mathrm{L}^{\prime}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ 3, equation (3). The facial geometry is conserved in the conversion of

$$
\begin{align*}
& 3\left[\mathrm{Re}^{\mathrm{IV}} \mathrm{~L}^{\left.\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]^{+}+\mathrm{H}_{2} \mathrm{O} \longrightarrow}\right. \\
& \text { fac- }\left[\mathrm{Re}^{\mathrm{IV}} \mathrm{~L}^{\prime}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]+2 \text { fac- }\left[\mathrm{Re}^{\mathrm{III}} \mathrm{~L}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]+3 \mathrm{H}^{+} \tag{3}
\end{align*}
$$

$\mathbf{1} \longrightarrow \mathbf{3}$, vide infra. When coulometry is performed in moist acetonitrile the regenerated $f a c-\left[\mathrm{Re}^{\mathrm{II}} \mathrm{L}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ complex, equation (3), is reoxidized and in this manner the whole of $\mathbf{1}$ is finally converted to 3 . The total coulomb count at full conversion corresponds to the transfer of three electrons. From the electrolytic solution $\mathbf{3}$ can be isolated in excellent yields.

These findings encouraged us to explore the chemical oxidation of $\mathbf{1}$ to $\mathbf{3}$. Aqueous nitric acid and hydrogen peroxide were indeed found to be very effective. The most convenient synthesis of $\mathbf{3}$ is based on aqueous nitric acid oxidation of $\mathbf{1}$ in acetonitrile solution.

Aldimine $\longrightarrow$ amide conversion in oxidizing aqueous environments has previously been observed ${ }^{2}$ in the cases of 2

Fig. 3 A view of $\left[\mathrm{ReL}^{4}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ 3d; the atoms are represented by their $30 \%$ thermal probability ellipsoids.

$$
\begin{aligned}
& \text { 3a }\left[\operatorname{ReL}^{1}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right](\mathrm{X}=\mathrm{H}) \\
& \text { 3b }\left[\operatorname{ReL}^{2}\left(\mathrm{PP}_{3}\right) \mathrm{Cl}_{3}\right](\mathrm{X}=\mathrm{Me}) \\
& \text { 3c }\left[\operatorname{ReL}^{3^{3}}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] \quad(\mathrm{X}=\mathrm{OMe}) \\
& \text { 3d }\left[\operatorname{ReL}^{4}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] \quad(\mathrm{X}=\mathrm{Cl})
\end{aligned}
$$

and $m e r-\left[\operatorname{ReL}(N A r) \mathrm{Cl}_{3}\right] .{ }^{5,6}$ Rate studies on $\mathbf{2}^{\mathbf{3}}$ and on a ruthenium system ${ }^{16}$ have demonstrated that the reaction proceeds by the addition of a molecule of water to the aldimine function polarized by metal oxidation. In the present case the oxidized metal is rhenium(IV) as in $\mathbf{1}^{+}$. Rapid oxidation of the corresponding water adduct $\mathbf{4}$ via induced transfer to two electrons ${ }^{17}$ associated with proton dissociation, can afford 3.

Spectral and magnetic data for $f a c-\left[\mathrm{Re}^{\mathrm{IV}} \mathrm{L}^{\prime}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] 3$ are listed in Table 1. The magnetic moments are lower ${ }^{3}$ than the $\mathrm{t}_{2 \mathrm{~g}}{ }^{3}$ (assuming idealised octahedral geometry) spin-only value. Two strong amide stretches occur in the range $1600-1640 \mathrm{~cm}^{-1}$. In dichloromethane solution 3 displays two quasi-reversible cyclic voltammetric responses in the range of -0.2 to 1.4 V corresponding to the couples $\operatorname{Re}^{\mathrm{IV}}-\mathrm{Re}^{\mathrm{II}}\left(E_{1 / 2} \approx-0.2 \mathrm{~V}\right)$ and $\mathrm{Re}^{\mathrm{V}}-$ $\operatorname{Re}^{\mathrm{IV}}\left(E_{1 / 2} \approx 1.4 \mathrm{~V}\right)$ (Table 4). Thus the $\mathrm{Re}^{\mathrm{IV}}-\mathrm{Re}^{\mathrm{II}}$ couple moves to lower potential by $\sim 700 \mathrm{mV}$ in going from $\mathbf{1}$ to $\mathbf{3}$ reflecting the ease of $\mathrm{Re}^{\mathrm{II}}-\mathrm{Re}^{\mathrm{IV}}$ oxidation upon amide binding.
The facial geometry of 3 has been proven by structure determination of $\left[\mathrm{ReL}^{4}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] \mathbf{3 d}$ (Fig. 3, Table 3). As in 1a the chelate ring, the pyridine ring and $\mathrm{Cl}(2), \mathrm{Cl}(3)$ atoms are coplanar (mean deviation $0.02 \AA$ ). The pendant aryl ring makes a dihedral angle of $68.9^{\circ}\left(50.1^{\circ}\right.$ in 1a) to the plane. The amide group $C(5) C(6) O(1) N(2)$ is nearly perfectly planar.

Contraction of the metal radius upon oxidation causes a $c a$. $0.06 \AA$ decrease in average $\mathrm{Re}-\mathrm{Cl}$ distances between $\mathbf{1 a}$ and $\mathbf{3 d}$. For comparison we note that between a similar phosphine
oxide pair both the $\mathrm{Re}-\mathrm{Cl}$ and $\mathrm{Re}-\mathrm{OPPh}_{3}$ (no back-bonding) bonds contract. ${ }^{2}$ In contrast the Re-P length increases by $0.1 \AA$ between 1a and 3d. This is primarily attributed to the weakening of $\mathrm{Re}-\mathrm{P}$ back-bonding upon metal oxidation. The residual interaction is, however sufficient to sustain facial geometry in $\mathbf{3}$ which fails to isomerise even on prolonged boiling in toluene.

## Conclusion

The fac-[ $\left.\mathrm{Re}^{\mathrm{III}} \mathrm{L}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] \mathbf{1}$ family having a facially configured $\operatorname{RePN} \mathrm{N}_{2} \mathrm{Cl}_{3}$ coordination sphere has been synthesized via ligand displacement from mer- $\left[\mathrm{Re}^{\mathrm{III}} \mathrm{L}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right]$ 2. The facial geometry of $\mathbf{1}$ is a result of the optimization of $\mathrm{Re}-\mathrm{PPh}_{3}$ and $\mathrm{Re}-\mathrm{L}$ back-bonding. The electrochemical and chemical oxidation of $\mathbf{1}$ is stereoretentive and has furnished $f a c-\left[\mathrm{Re}^{\mathrm{IV}} \mathrm{L}^{\prime}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] \mathbf{3}$ in which the rhenium(IV) state is stabilized by amide bonding. The Re- P back-bonding and bond length orders are respectively $\mathbf{1 > 3}$ and $\mathbf{1 < 3}$.

## Experimental

## Materials

$\left[\operatorname{ReL}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right],{ }^{3}\left[\mathrm{ReOCl}_{3}\left(\mathrm{PPh}_{3}\right)_{2}\right]^{18}$ and pyridine-2-aldimine ${ }^{19}$ were prepared by reported methods. The purification and drying of dichloromethane and acetonitrile for synthesis as well as for electrochemical work were done as described. ${ }^{20}$ Toluene and benzene were distilled over sodium before use. All other chemicals and solvents were of reagent grade and used as received.

## Physical measurements

Spectra were recorded with the following equipment: electronic spectra, Hitachi 330 spectrophotometer; infrared spectra ( KBr disc, 4000-300 $\mathrm{cm}^{-1}$ ), Perkin-Elmer 783 spectrophotometer, proton NMR spectra were recorded on a Bruker FT 300 MHz spectrometer. Electrochemical measurements were done by using a PAR model 370-4 electrochemistry system as described. ${ }^{13 b}$ All experiments were performed at a platinum working electrode under a dinitrogen atmosphere, the supporting electrolyte being tetraethylammonium perchlorate. The potentials are referenced to the saturated calomel electrode (SCE) and are uncorrected for the junction contribution. Magnetic susceptibilities were measured on a PAR-155 vibrating sample magnetometer. Microanalyses were done by using a Perkin-Elmer 240C elemental analyser.

## Syntheses

$\boldsymbol{f a c}-\left[\operatorname{Re}^{\mathrm{III}} \mathbf{L}\left(\mathbf{P P h}_{3}\right) \mathbf{C l}_{3}\right]$ 1. The complexes were prepared by the same general methods. Details are given for $\mathbf{1 b}\left(\mathrm{L}=\mathrm{L}^{2}\right)$.

To a pink solution of $m e r-\left[\operatorname{ReL}^{2}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right](100 \mathrm{mg}, 0.14$ $\mathrm{mmol})$ in dry benzene $\left(15 \mathrm{~cm}^{3}\right), \mathrm{PPh}_{3}(200 \mathrm{mg}, 0.75 \mathrm{mmol})$ was added and the mixture was heated to reflux under pure nitrogen for 1 h affording a violet solution which yielded crystalline fac$\left[\operatorname{ReL}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right](20 \mathrm{mg})$ upon cooling to room temperature. The complex was collected by filtration and the filtrate was stripped of solvent. The residue was dissolved in a small volume of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and subjected to chromatography on a silica gel column prepared in benzene. Upon elution with benzeneacetonitrile $(25: 1,15: 1$ and $10: 1)$ mer- $\left[\operatorname{ReL}^{2}\left(\mathrm{OPPh}_{3}\right) \mathrm{Cl}_{3}\right](18$ $\mathrm{mg})$, mer- $\left[\operatorname{ReL}^{2}\left(\mathrm{NC}_{6} \mathrm{H}_{4} \mathrm{Me}\right) \mathrm{Cl}_{3}\right](7 \mathrm{mg})$ and fac- $\left[\operatorname{ReL}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ $(28 \mathrm{mg})$ were successively isolated. The total yield of bluish violet fac-[ $\left.\operatorname{ReL}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ is $48 \mathrm{mg}, 50 \%$.

The complex was also synthesized starting from a solution of $\left[\mathrm{ReOCl}_{3}\left(\mathrm{PPh}_{3}\right)_{2}\right](100 \mathrm{mg}, 0.12 \mathrm{mmol})$ in dry benzene $\left(15 \mathrm{~cm}^{3}\right)$ containing $\mathrm{L}^{2}(29 \mathrm{mg}, 0.15 \mathrm{mmol})$. The mixture was heated to reflux under pure nitrogen for 1 h . The violet solution was stripped of solvent and the residue subjected to chromatography as described above. The yield of $f a c-\left[\operatorname{ReL}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$
was $37 \mathrm{mg}, 40 \%$ (Found: C, 48.95 ; H, 3.25; N, 3.70. Calc. for $\mathrm{C}_{30} \mathrm{H}_{25} \mathrm{Cl}_{3} \mathrm{~N}_{2}$ PRe 1a: C, $48.87 ; \mathrm{H}, 3.39$; N, 3.80. Found: C, 48.68; $\mathrm{H}, 3.51$; N, 3.61. Calc. for $\mathrm{C}_{31} \mathrm{H}_{27} \mathrm{Cl}_{3} \mathrm{~N}_{2}$ PRe 1b: C, 49.56; H, 3.60; N, 3.73. Found: C, $48.40 ; \mathrm{H}, 3.35 ; \mathrm{N}, 3.50$. Calc. for $\mathrm{C}_{31} \mathrm{H}_{27} \mathrm{Cl}_{3} \mathrm{~N}_{2}$ OPRe 1c: C, 48.52; H, 3.52; N, 3.65. Found: C, $47.00 ; \mathrm{H}, 3.25 ; \mathrm{N}, 3.50$. Calc. for $\mathrm{C}_{30} \mathrm{H}_{24} \mathrm{Cl}_{4} \mathrm{~N}_{2}$ PRe 1d: C, 46.69 ; H, 3.11; N, 3.63\%).
$\boldsymbol{f a c}-\left[\mathbf{R e}^{\mathrm{IV}} \mathbf{L}^{\prime}\left(\mathbf{P P h}_{3}\right) \mathbf{C l}_{3}\right]$ 3. The same general methods were used for all the complexes. The case of $\mathbf{3} \mathbf{b}\left(\mathrm{L}^{\prime}=\mathrm{L}^{2^{\prime}}\right)$ is detailed below.

A solution of $f a c-\left[\mathrm{Re}^{\mathrm{II}} \mathrm{L}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right](20 \mathrm{mg}, 0.027 \mathrm{mmol})$ in wet acetonitrile $\left(20 \mathrm{~cm}^{3}\right)$ containing tetraethylammonium perchlorate ( $25 \mathrm{mg}, 0.11 \mathrm{mmol}$ ) was electrolyzed exhaustively under nitrogen at 1.0 V vs. SCE. The bluish violet solution changed to red and finally to yellow. The coulomb count corresponded to the transfer of three electrons, equation (4)

$$
\begin{align*}
f a c-\left[\mathrm{Re}^{\mathrm{III}} \mathrm{~L}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right] & \longrightarrow a c-\left[\mathrm{Re}^{\mathrm{IV}} \mathrm{~L}^{\prime}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]+3 \mathrm{H}^{+}+3 \mathrm{e}^{-}
\end{align*}
$$

(observed count, 7.25; calculated count for one electron, 2.45).

The electrolyzed solution was stripped of the solvent and the residue was washed thoroughly with hot water and then dried over $\mathrm{P}_{4} \mathrm{O}_{10}$, yielding pure yellow fac-[ $\left.\operatorname{ReL}^{2^{\prime}}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$. The yield was $14 \mathrm{mg}, 72 \%$.

Chemical synthesis of the complex was achieved by oxidation of $f a c-\left[\operatorname{ReL}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right](50 \mathrm{mg}, 0.067 \mathrm{mmol})$ in acetonitrile (20 $\mathrm{cm}^{3}$ ) by aqueous $\mathrm{HNO}_{3}\left(0.5 \mathrm{M}, 0.5 \mathrm{~cm}^{3}\right)$. The mixture was stirred for 1 h at room temperature affording a yellow solution [hydrogen peroxide $\left(0.5 \mathrm{~cm}^{3}, 30 \%\right)$ requires 12 h stirring in an ice bath]. The solvent was removed and the residue washed and dried as above, yielding fac- $\left[\operatorname{ReL}^{2^{\prime}}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$. The yield was $40 \mathrm{mg}, 80 \%$ (Found: C, $47.80 ; \mathrm{H}, 3.25 ; \mathrm{N}, 3.60$. Calc. for $\mathrm{C}_{30} \mathrm{H}_{24} \mathrm{Cl}_{3} \mathrm{~N}_{2}$ OPRe 3a: C, 47.89; H, 3.19; N, 3.73. Found: C, 48.80; H, 3.25; N, 3.50. Calc. for $\mathrm{C}_{31} \mathrm{H}_{25} \mathrm{Cl}_{3} \mathrm{~N}_{2} \mathrm{OPRe} 3 \mathrm{bb}$ : C, 48.58; H, 3.40; N, 3.66. Found: C, $47.50 ; \mathrm{H}, 3.42 ; \mathrm{N}, 3.45$. Calc. for $\mathrm{C}_{31} \mathrm{H}_{26} \mathrm{Cl}_{3} \mathrm{~N}_{2} \mathrm{O}_{2}$ PRe 3c: C, 47.59; H, 3.33; N, 3.58. Found: C, 46.00; H, 2.80; N, 3.65. Calc. for $\mathrm{C}_{30} \mathrm{H}_{23} \mathrm{Cl}_{4} \mathrm{~N}_{2}$ OPRe 3d: C, 45.79; H, 2.93; N, 3.56\%).

## Conversion of fac- $\left[\operatorname{Re}^{\mathrm{III}} \mathrm{L}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right]$ to $m e r-\left[\operatorname{Re}^{\mathrm{V}} \mathbf{L}^{2}\left(\mathrm{NC}_{6} \mathbf{H}_{4} \mathbf{M e}\right)\right.$ $\mathrm{Cl}_{3}$ ]

A solution of $f a c-\left[\operatorname{ReL}^{2}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}_{3}\right](50 \mathrm{mg}, 0.067 \mathrm{mmol})$ in toluene ( $10 \mathrm{~cm}^{3}$ ) was heated to reflux for 1 h in the presence of $p$-toluidine ( $35 \mathrm{mg}, 0.33 \mathrm{mmol}$ ). The violet solution was stripped of solvent and the residue was subjected to chromatography on a silica gel column using benzene-acetonitrile (15:1) as the eluent. The complex mer- $\left[\operatorname{ReL}^{2}\left(\mathrm{NC}_{6} \mathrm{H}_{4} \mathrm{Me}\right) \mathrm{Cl}_{3}\right]$ was isolated (yield $35 \mathrm{mg}, 88 \%$ ) by removing the solvent.

## Crystallography

Dark prismatic crystals of $\mathbf{1 a}$ and orange prismatic crystals of 3d were grown by slow diffusion of hexane into dichloromethane solutions of the respective complexes.

Cell parameters were determined by a least-squares fit of 30 machine-centered reflections $\left(2 \theta=15-30^{\circ}\right)$. Data were collected by the $\omega$-scan technique in the range $3 \leqslant 2 \theta \leqslant 45^{\circ}$ for 1 a and $3 \leqslant 2 \theta \leqslant 47^{\circ}$ for $\mathbf{3 d}$ on a Siemens R3m/V four-circle diffractometer with graphite-monochromated Mo-K $\alpha$ radiation $(\lambda=0.71073 \AA$ ). Two check reflections after every 198 showed no intensity reduction. All data were corrected for Lorentzpolarization and absorption. ${ }^{21}$ The metal atoms were located from Patterson maps, and the rest of the non-hydrogen atoms emerged from successive Fourier syntheses. The structures were then refined by a full-matrix least-squares procedure on $F^{2}$. All non-hydrogen atoms [except $\mathrm{O}(2)$ for 3 d ] were refined anisotropically. All hydrogen atoms were included in calculated
