#### Abstract

The chelating behaviour of three polyphosphines, cone-5,11,17,23-tetra-tert-butyl-25,26,27,28-tetrakis(diphenylphosphinomethoxy)calix[4]arene L ${ }^{1}$, cone-5,11,17,23-tetra-tert-butyl-25,26,27-tris(diphenylphosphinomethoxy)-28-methoxycalix[4]arene $\mathrm{L}^{2}$, and cone-5,11,17,23-tetra-tert-butyl-25,26-bis(diphenylphosphinomethoxy)-27,28dihydroxycalix[4]arene $\mathrm{L}^{3}$, has been investigated. When $\left[\mathrm{Mo}(\mathrm{CO})_{3}\left(\mathrm{C}_{7} \mathrm{H}_{8}\right)\right]$ and tetraphosphine $\mathrm{L}^{1}$ are heated together under reflux in tetrahydrofuran (THF) complex $\left[\mathrm{Mo}(\mathrm{CO})_{3} \mathrm{~L}^{1}\right] \mathbf{1}$ is formed, for which the calixarene behaves as a fac-bonded tridentate ligand with one phosphine remaining free. Similar fac-chelating behaviour is found with $\left[\mathrm{Mo}(\mathrm{CO})_{3} \mathrm{~L}^{2}\right] \mathbf{2}$, which is obtained from triphosphine $\mathrm{L}^{2}$. Formation of this latter complex is accompanied by the calixarene matrix adopting a partially flattened-cone conformation. In contrast, the conventional cone conformation is maintained in the trinuclear complex $\left[\left(\mathrm{AuCl}_{3} \mathrm{~L}^{2}\right] \mathbf{3}\right.$, obtained quantitatively by treating $\mathrm{L}^{2}$ with $[\mathrm{AuCl}(\mathrm{THT})](\mathrm{THT}=$ tetrahydrothiophene $)$. Reaction of $\mathrm{L}^{1}$ with $\left[\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}\right]\left(\mathrm{DMSO}=\mathrm{Me}_{2} \mathrm{SO}\right)$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ results in selective formation of the deep purple complex $\left[\mathrm{RuCl}_{2} \mathrm{~L}^{2}\right] 4$ built around a fac-trigonal bipyramidal $\mathrm{RuCl}_{2} \mathrm{P}_{3}$ structure. Complex $\mathbf{4}$ reacts reversibly and stepwise with two equivalents of $\mathrm{CH}_{3} \mathrm{CN}$. The calculated stability constants, as determined from a spectrophotometric titration, are $\log \beta_{1}=9.1$ and $\log \beta_{2}=12.4$. The proximally substituted calixarene $\mathrm{L}^{3}$ reacts with $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right](\mathrm{COD}=$ cycloocta-1,5-diene) to afford the chelate complex cis- $\left[\mathrm{PtCl}_{2} \mathrm{~L}^{3}\right] 5$. As revealed by an X-ray diffraction study, the $\mathrm{P}-\mathrm{Pt}$ vectors point away from the calixarene axis in the solid state. The axial H atom of the $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ group located between the two phosphine units of $\mathrm{L}^{3}$ undergoes a significant low-field shift upon complexation ( $\delta 7.32$ vs. 4.48 for free $L^{3}$ ) presumably due to interaction with the lone pairs of the two neighbouring O -atoms. Complex $\mathbf{5}$ displays dynamic behaviour in solution, which can be rationalized as follows: (i) a fast flip-flop motion of the hydroxyl groups at low temperature, alternately forming hydrogen bonds with each of two neighbouring phenolic oxygens; (ii) a reversible inversion of the phenol ring through the lower-rim annulus, triggered by breakage of the hydrogen bonds at higher temperature. Reaction of $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$ with one equivalent of $\mathrm{L}^{1}$, followed by in situ oxidation with $\mathrm{NH}_{2} \mathrm{CONH}_{2} \cdot \mathrm{H}_{2} \mathrm{O}_{2}$, results in formation of a chelate complex, containing two proximal phosphines bonded to platinum as in $\mathbf{5}$ and two pending $\mathrm{CH}_{2} \mathrm{P}(\mathrm{O}) \mathrm{Ph}_{2}$ phosphine oxides. Stepwise reaction of $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$ with one equivalent of $\mathrm{L}^{1}$ and two equivalents of $[\mathrm{AuCl}(\mathrm{THT})]$ gives a cis complex in which the platinum atom is again bonded to two proximal phosphines and the two AuCl units to the other two phosphine arms. As in 5, an anomalous low-field shift is observed for the axial $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}$ belonging to the platinocycle of these complexes.

Macrocyclic platforms that contain several phosphino groups attached to their periphery are powerful tools for the construction and study of multimetal species that contain discrete metal centres maintained in close proximity. ${ }^{1-5}$ In particular, several recent publications have described the properties of the p-tert-butylcalix[4]arene-derived tetraphosphine $\mathrm{L}^{1}$, a ligand containing four pendant $\mathrm{CH}_{2} \mathrm{PPh}_{2}$ units that can bind up to four transition metal centres. ${ }^{1,6,7}$ It has also been reported that,

[^0]in certain cases, $\mathrm{L}^{1}$ behaves as a small $\mathrm{P}_{4}$ surface around which several gold or silver ions can migrate rather easily. These prior studies have revealed that individual metal centres may be bonded to $\mathrm{L}^{1}$ by way of either a single pendant phosphorus(III) unit or with two adjacent P atoms functioning as cis or trans chelators. No instance could be found whereby three phosphorus atoms co-ordinate to a single metal centre. Such tripodal co-ordination, which is described here for the first time, results in formation of two adjacent 12 -membered metallocycles and in the fixation of a metal centre at the apex of the calixarene cavity. The current study also focuses on the structural implications associated with co-ordination of a metal centre to two adjacent $\mathrm{CH}_{2} \mathrm{PPh}_{2}$ phosphine units tethered at the lower rim of the calix[4]arene platform. This complements earlier work on distal co-ordination of substituted calix[4]arenes. ${ }^{8,9}$

$\mathbf{L}^{1}$

## Results and discussion

## Tripodal behaviour of calix[4]arene polyphosphines

Should we expect tridentate co-ordination to a single transition metal centre by a calix[4]arene substituted at the lower rim by three or four $\mathrm{CH}_{2} \mathrm{PPh}_{2}$ groups? At first sight such ligation seems unlikely since it requires formation of two 12 -membered metallo-macrocycles. To reach a more definitive answer, however, we have examined the co-ordinative properties of two suitably functionalized ligands, namely tetraphosphine $\mathrm{L}^{1}$ and triphosphine $\mathrm{L}^{2}$, towards two metal fragments, " $\mathrm{Mo}(\mathrm{CO})_{3}$ " and " $\mathrm{RuCl}_{2}$ ", known to form tris(phosphine) complexes. ${ }^{10,11}$ Ligand $\mathrm{L}^{2}$, which is reported for the first time, was prepared in high yield by reduction of the corresponding tris(phosphine oxide) ${ }^{6}$ $\mathrm{L}^{2}{ }_{\mathrm{ox}}$ with phenylsilane (Scheme 1) using a known general pro-

cedure. Signals for the phosphine units appear at $\delta-17.3$ (2P) and $-18.6(1 \mathrm{P})$ in the ${ }^{31} \mathrm{P}$ NMR spectrum whilst the calixarene fragment adopts a cone conformation as deduced from the ${ }^{13} \mathrm{C}$ NMR spectrum. This latter assignment is based on the following reasoning: $\mathrm{CH}_{2}$ groups that bridge two aryl rings in a relative syn arrangement exhibit chemical shifts in the range $\delta 29-33^{12}$ whereas the $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ signal for anti-oriented aryl rings in partial-cone conformers appears at higher values (in general $\delta>c a$. 37). We are aware that these guidelines, being most helpful for establishing the conformation of calix[4]arenes, must be applied with care in those cases where the phenolic units of the calixarene are not possessed of bulky substituents. ${ }^{13}$ This is because phenolic rings bearing small substituents can undergo fast transannular rotation around the bridging methylene groups or, in certain cases, adopt an orientation that positions the substituent inside the calix cavity. For both situations the chemical shift of the bridging $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ groups lies between $\delta 33$ and 37 . Even so, it seems reasonable to assign a cone conformation to ligand $L^{2}$. Relevant spectroscopic data for $\mathrm{L}^{2}$ are given in the Experimental section.

Reaction of $\mathrm{L}^{1}$ with $\left[\mathrm{Mo}(\mathrm{CO})_{3}\left(\mathrm{C}_{7} \mathrm{H}_{8}\right)\right]$ in refluxing tetrahydrofuran (THF) afforded the colourless complex 1 in high yield. The fact that no oligomers are formed, regardless of reaction conditions, is a good indication for the high degree of preorganization of the three podands. The tridentate behaviour of $L^{1}$ was inferred from the ${ }^{31} \mathrm{P}$ NMR spectrum which shows two signals of relative intensity $2: 1$ corresponding to metal-bound phosphines $\left({ }^{2} J(\mathrm{PP})=13 \mathrm{~Hz}\right)$ and a singlet at $\delta-18.7$ (intensity

1P) assignable to an unco-ordinated $\mathrm{P}^{\mathrm{III}}$ atom. The carbonyl region of the IR spectrum shows two strong absorption bands indicating the presence of a $\mathrm{Mo}(\mathrm{CO})_{3}$ unit with local $C_{3 \mathrm{v}}$ symmetry. ${ }^{10}$ The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectral data reveal the presence of two distinct $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ fragments but the relevant ${ }^{13} \mathrm{C}$ chemical shifts ( $\delta 32.06$ and 31.30 ) are fully consistent with a cone conformation. Similarly, the AB patterns observed for each set of $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ groups correspond to a splitting of the A and B parts ( $\delta_{\mathrm{A}}-\delta_{\mathrm{B}}=1.47$ and 1.05 ) that is further confirmation for a cone conformation: ${ }^{14}$ syn-oriented aryl rings usually give AB separations > ca. 0.7 ppm , while the AB separation is smaller for anti-oriented aryl rings.

2

3

For triphosphine $L^{2}$, reaction with $\left[\mathrm{Mo}(\mathrm{CO})_{3}\left(\mathrm{C}_{7} \mathrm{H}_{8}\right)\right]$ in refluxing THF led to complex 2 ( $58 \%$ ), which also contains a $f a c-\mathrm{MoP}_{3}$ unit. There was no indication for oligomer formation in this reaction. The FAB mass spectrum of the complex displays peaks at $m / z 1438$ and 1410 , with the profile exactly matching that expected for the $\mathrm{M}^{+}$and $[\mathrm{M}-\mathrm{CO}]^{+}$cations, respectively. The ${ }^{13} \mathrm{C}$ NMR spectrum displays two distinct $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ signals at $\delta 30.22$ and 35.46 . The former value is typical of a $\mathrm{CH}_{2}$ group bordered by syn-arranged aryl rings whereas the latter value lies between those reported for syn and anti $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{2}$ arrangements. It seems likely, therefore, that the calix matrix adopts a partially flattened conformation with the methoxy group being oriented towards the calix axis and entrapped between two facing aryl units. Indeed, the strong upfield shift experienced by the methoxy protons ( $\delta 0.38$, $\Delta \delta=-3 \mathrm{ppm}$ ) reflects their encapsulation between aromatic rings. Finally, we note that one set of $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ groups appears as an $A B$ pattern with an $A B$ separation of only 0.50 ppm . No significant structural change was apparent from NMR spectra recorded over the temperature range -80 to $+25^{\circ} \mathrm{C}$. It is difficult to explain the different calix conformations adopted by $\mathbf{1}$ and 2, especially when allowing for the observation that $\mathrm{L}^{2}$ reacts with 3 equivalents of $[\mathrm{AuCl}(\mathrm{THT})]$ ( $\mathrm{THT}=$ tetrahydrothiophene) to form the trinuclear species $\mathbf{3}$ which persists in the cone conformation. The major difference between 2 and $\mathbf{3}$ is that the P atoms are assembled in one complex via a central atom whereas they move as three independent arms in the other. Clearly, a structure with fac co-ordinated phosphines results in a more strained calix matrix favouring a partially flattened conformation. The latter was not observed in 1 obviously

Fig. 1 Spectrophotometric titration of complex 4 by $\mathrm{CH}_{3} \mathrm{CN}$. Conditions: $[4]_{\text {initial }}=5 \times 10^{-4} \mathrm{M}$. Solvent: $\mathrm{CH}_{2} \mathrm{Cl}_{2}$.
because the $\mathrm{CH}_{2} \mathrm{PPh}_{2}$ group is sterically much larger than a Me group. Thus, a subtle balance between the bulk of the nonmetallated phenoxy substituent and the strain within the calix backbone explains the different structures adopted by complexes 1-3.

Reaction of $\mathrm{L}^{1}$ with $\left[\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}\right]\left(\mathrm{DMSO}=\mathrm{Me}_{2} \mathrm{SO}\right)$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}\left(25^{\circ} \mathrm{C}\right)$ is very slow but leads to selective formation of the deep purple complex 4. After 15 d the yield reached $60 \%$. The FAB mass spectrum of $\mathbf{4}$ shows a peak at $m / z 1577$ corresponding to the $[\mathrm{M}-\mathrm{Cl}]^{+}$cation. That only a monomeric species is formed was apparent from vapour phase osmometry. In the ${ }^{31} \mathrm{P}$ NMR spectrum the unco-ordinated phosphine appears at $\delta-20.0$ while the three bound phosphorus atoms give rise to an $\mathrm{A}_{2} \mathrm{~B}$ pattern with $\delta_{\mathrm{A}}=35.4$ and $\delta_{\mathrm{B}}=60.3$. The purple colour of the complex is a good indication for a fac-trigonal bipyramidal $\mathrm{RuCl}_{2} \mathrm{P}_{3}$ structure. ${ }^{11,15}$ Further proof for the mutual cis arrangement of the three phosphorus atoms includes: (i) the ${ }^{2} J\left(\mathrm{P}^{\mathrm{A}} \mathrm{P}^{\mathrm{A}^{\top}}\right)$ value, $c a .25 \mathrm{~Hz}$, calculated from the ${ }^{13} \mathrm{C}$ NMR signal (a quintet) of the two distal $\mathrm{PCH}_{2}$ groups and (ii) the ${ }^{2} J\left(\mathrm{P}^{\mathrm{A}} \mathrm{P}^{\mathrm{B}}\right)$ value of 41 Hz as obtained from the ${ }^{31} \mathrm{P}$ NMR spectrum. Note that the overall structure of $\mathbf{4}$ is reminiscent of that of 1. There is no indication for fluxional behaviour or isomerization of $\mathbf{4}$ in solution. In contrast, reaction of triphosphine $\mathrm{L}^{2}$ with $\left[\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}\right]$ afforded a mixture of products, presumed to be oligomers, that could not be resolved. The NMR spectra do not change when running them at different concentrations. Thus monomer-oligomer equilibria can be ruled out.

Addition of a few drops of $\mathrm{CH}_{3} \mathrm{CN}$ to a solution of complex 4 in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ caused an instantaneous change to pale yellow. Evaporation of the solvent fully regenerated 4. Attempts to isolate a complex formed with $\mathrm{CH}_{3} \mathrm{CN}$ were unsuccessful but spectrophotometric titrations (Fig. 1) established that $\mathbf{4}$ reacts stepwise with two molecules of $\mathrm{CH}_{3} \mathrm{CN}$. The calculated stability constants are $\log \beta_{1}=9.1 \pm 0.2$ and $\log \beta_{2}=12.4 \pm 0.5$, indicating that addition of the first solvent molecule is exceptionally favourable, corresponding to a binding energy of $50 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Addition of a second acetonitrile molecule is more
difficult. Interestingly, the mono-adduct does not absorb in the region $450-650 \mathrm{~nm}$ but the bis-adduct absorbs over this range, suggesting different geometries.

## Chelating behaviour of two proximally positioned $\mathbf{C H}_{2} \mathbf{P P h}_{2}$ groups

Tripodal ligation of the type expressed in complexes $\mathbf{1}$ and $\mathbf{4}$ forces the metallic centre to reside beneath the lower rim of the calix cavity. Related complexes are known for which the metal centre is chelated by two distally tethered $\mathrm{CH}_{2} \mathrm{PPh}_{2}$ podands ${ }^{16}$ and a logical extension of this work is to design suitable 1,2disubstituted calixarenes equipped with two proximal $\mathrm{CH}_{2} \mathrm{PPh}_{2}$ groups. The simplest such representative is the diphosphine $\mathrm{L}^{3}$, which was obtained in quantitative yield by reduction of the corresponding di(phosphine oxide) ${ }^{6} \mathrm{~L}^{3}$ ox with $\mathrm{PhSiH}_{3}$. Clear evidence for the cone conformation was obtained from ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra. In particular, the ${ }^{1} \mathrm{H}$ NMR spectrum shows three AB systems for the $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ groups, with AB separations of 1.39, 1.21 and 0.83 ppm (relative intensity $2 \mathrm{H}: 4 \mathrm{H}: 2 \mathrm{H}$ ). The signal for the two residual OH groups appears at $\delta 8.91$ ( $c f$. $\delta 5.50$ for $p$-tert-butylphenol and 10.34 for $p$-tert-butylcalix[4]arene), suggesting their involvement in hydrogen bonding with neighbouring phenolic oxygen atoms.
Reaction of $\mathrm{L}^{3}$ with $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$ (COD $=$ cycloocta-1,5diene) in dichloromethane afforded complex 5 in $72 \%$ yield after chromatography (Scheme 2). To prevent formation of

Scheme 2
oligomers, reaction was carried out at modest concentration. In this complex the platinum centre forms part of a 12 -membered metallo-macrocycle. The NMR spectral data collected indicate a plane of symmetry. For example, the ${ }^{1} \mathrm{H}$ NMR spectrum shows three sets of $A B$ patterns for the $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ groups and two $\mathrm{Bu}^{\mathrm{t}}$ signals. The cis stereochemistry around platinum was inferred from the $J(\mathrm{PPt})$ coupling constant of 3672 Hz . Interestingly, the $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ group lying between the two phosphines gives rise to an AB system with an exceptionally large splitting of the A and B parts: ca. 3.6 ppm (!). The corresponding axial H atom was found at $c a . \delta 7.34$. The assignment of this particular AB signal was made on the basis of a two-dimensional ROESY (rotating frame Overhauser enhancement spectroscopy) experiment (at 218 K ). We note also that the ${ }^{13} \mathrm{C}$ NMR signal ( $\delta 36.98$ ) for the $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ group within the metallocycle (as identified by an HETCOR (heteronuclear correlation) experiment) lies considerably outside the range expected for methylene groups bordered by syn oriented aryl rings.

Note that Floriani and co-workers ${ }^{17}$ have recently reported that the axial $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}$ hydrogen of the 10 -membered metallocycles present in complex $\mathbf{6}$ undergoes also an anomalous downfield shift ( $\delta_{\mathrm{A}} 5.86$ ) with respect to the "free" ligand. This phenomenon which was attributed to ring current effects generated by the metallomacrocycles is however less important than that observed in 5 . In order to identify other effects that could account for the rather unusual downfield shift observed for 5 and also to clarify the mutual positioning of the metal centre and the cavity ( $\mathbf{A}$ or $\mathbf{B}$ form), an X-ray diffraction study was

Fig. 2 Molecular structure (PLATON ${ }^{18}$ ) of complex 5.

6

A

B
carried out for 5. The result of this investigation is shown in Fig. 2. ${ }^{18}$

The X-ray analysis confirmed the chelating behaviour of $\mathrm{L}^{3}$ and established the cone conformation. This complex crystallizes with one molecule of water and six molecules of dichloromethane, one of which lies inside the cavity. The two PPt vectors are directed away from the centre of the cavity, so that the two bound chlorides lie well away from the lower rim (B form), with the result that the Pt atom lies $2.67 \AA$ beneath the axial $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}$ proton. Note, this distance might be too long for agostic interaction, although in solution shorter separations will abound. It is notable that the axial $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}$ atom, which is located between the two P atoms, resides only $2.42 \AA$ from the two neighbouring phenolic O atoms. Although on the upper limit for hydrogen bonding, we cannot rule out the possibility of weak interactions between these atoms. These

could then explain the observed low-field shift. The rather short $\mathrm{O}(1) \cdots \mathrm{O}(4), \mathrm{O}(3) \cdots \mathrm{O}(4)$ and $\mathrm{O}(2) \cdots \mathrm{O}(3)$ distances (respectively $2.90,2.67$ and $2.78 \AA$, Table 1 ) are indicative of hydrogen bonding between the hydroxy functions and the adjacent phenolic O atoms. The calixarene matrix is close to that found in an ideal cone. This is in marked contrast to the structure of the non-metallated oxidized form of $\mathrm{L}^{3}$ (Fig. 3, Table 2) which displays the conventional flattened cone shape found in the solid state for most calix[4]arenes. The idealized cone conformation seen for the matrix in 5 probably arises from a combination of effects caused by the presence of the strained metallocycle and the $\mathrm{O} \cdots \mathrm{HO}$ bridges.

A variable temperature NMR study $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}, 500 \mathrm{MHz}\right.$, Fig. 4) carried out between 198 and 308 K revealed that complex 5 undergoes a structural modification in solution on varying the temperature. The low temperature ${ }^{1} \mathrm{H}$ NMR spectra are fully consistent with a cone conformation (e.g. large separations for the $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ groups at 198 K ). On raising the temperature the two sets of $A B$ signals corresponding to the $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ groups centred on C59 and $\mathrm{C}(48) / \mathrm{C}(70)$ (for labelling see Fig. 2; for simplification these atoms are respectively labelled \# and * in Fig. 4) begin to broaden, reaching a maximum of broadening around 238 K , and eventually reappearing as two new sets of
 ing to the $\mathrm{PCH}_{2}$ and $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{2}$ protons. The symbols $*$, \# and $\Delta$ have been used for indexing the bridging $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{2}$ protons. The signal of the axial $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}$ atom belonging to the platinomacrocycle is out of this view $(\delta 7.34,308 \mathrm{~K})$.

Scheme 3 Proposed dynamics for complex 5.

AB signals. At the highest temperature these AB separations are much smaller ( $\Delta \delta=0.56$ and $0.36 \mathrm{ppm}, \mathrm{CD}_{2} \mathrm{Cl}_{2}, 308 \mathrm{~K}$ ) than in the low temperature spectra, thus indicative for the formation of a structurally different isomer. The smaller AB splittings could arise from formation of fast interconverting 1,2-alternate conformers or because of fast equilibration between cone and non-cone species. The third AB system, which corresponds to H atoms bonded to C 24 (only the B part, labelled $\Delta$, is shown in Fig. 4) remains essentially unperturbed over this temperature range. To help interpret the high temperature spectra, two-dimensional ROESY experiments $\ddagger$ were performed on 5 and its $\mathrm{PMe}_{2}$ analogue 7. This latter complex is a useful model by which to explain the various NMR spectral changes because the only aromatic hydrogens able to correlate with $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ protons are those belonging to the calix matrix. In fact the NMR spectrum recorded for 7 shows NOEs between a $m-\mathrm{CH}$ of the phenol rings and both doubly degenerated $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ protons (labelled

[^1]
*). This observation can be explained only in terms of rapid inversion of the phenol rings.

The spectral modifications observed for complex 5 in the range $198-308 \mathrm{~K}$ are reversible and may be rationalized in terms of disruption of the hydrogen bonds as the sample is heated, followed by ring inversion at higher temperatures (Scheme 3). Interestingly, on raising the temperature, one of the $\mathrm{PCH}_{2}$ hydrogen atoms undergoes a significant change in chem-
ical shift while the other is little affected (Fig. 4). This behaviour would occur if one CH atom is anti oriented with respect to the interacting OH atom. The low temperature spectra indicate a $C_{\mathrm{s}}$-symmetrical cone structure with hydrogen bonded OH groups ( $\delta 8.46$ at 218 K ). Furthermore, two-dimensional ROESY experiments performed at low temperature show that the OH atoms correlate with the axial CH atoms of both neighbouring $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ groups. These findings are in agreement with a fast flip-flop motion of the hydroxyl groups, as shown in Scheme 3 (left side). This movement which could not be frozen out is reminiscent of the hydroxyl movement observed in native $\beta$-cyclodextrin. ${ }^{19}$ The free enthalpy of activation for the interconversion between the isomer containing hydrogen bonds and that obtained after hydrogen bond breaking ( $T=238 \mathrm{~K}$ ) is calculated ${ }^{20}$ to be $58 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Note, hydrogen bond breaking involving phenolic OH groups in calixarenes is well documented; for comparison, the energy barrier for cone-cone interconversion of $p$-tert-butylcalix[4]arene, a process that implies the rupture of four hydrogen bonds (followed by inversion of the calix matrix), is $70-75 \mathrm{~kJ} \mathrm{~mol}^{-1} .^{21,22}$ Important conformational changes within the metallomacrocycle itself appear unlikely since the $A B$ separation of the endocyclic $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ group remains essentially unchanged during the temperature variation. However, flipping of the platinum atom under the calix cavity (with exchange between the $\mathbf{A}$ and $\mathbf{B}$ forms) cannot strictly be ruled out. In summary, the modification observed in the NMR spectra of complex $\mathbf{5}$ may be interpreted in terms of hydrogen bond breaking when the temperature is raised Thus, we observe the reversible conversion of a species "with hydrogen bonds" into an isomer "without hydrogen bonds". Both isomers undergo fast dynamics involving either hydroxyl movement (low temperature species) or phenol ring inversion (high temperature isomer).

A detailed ${ }^{31} \mathrm{P}$ NMR spectroscopic investigation was made of the reaction between one equivalent of tetraphosphine $\mathrm{L}^{1}$ and $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$. The resultant platinum complex comprises two cis-co-ordinated P atoms ( $\delta 8.9, J(\mathrm{PPt})=3640 \mathrm{~Hz}$ ) and two free phosphines $(\delta-19.6)$. Attempts to isolate this compound were unsuccessful because oligomerization occurred during concentration. To overcome this problem, $\mathrm{NH}_{2} \mathrm{CONH}_{2} \cdot \mathrm{H}_{2} \mathrm{O}_{2}$ was added to the reaction mixture after one hour (Scheme 4). This procedure results in mild oxidation of the unco-ordinated
phosphine arms and afforded complex $\mathbf{8}$ in high yield (Scheme $4 a)$. FAB mass spectrometry revealed peaks due to both $\mathrm{M}^{+}$ and $[\mathrm{M}-\mathrm{Cl}]^{+}$while ROESY, COSY and HETCOR experiments allowing precise assignment of all hydrogen atoms, except those of the PPh groups (see Experimental section). The ${ }^{31} \mathrm{P}$ NMR spectrum recorded for $\mathbf{8}$ displays a signal centred at $\delta 8.6$ (cf. 8.4 for 5), attributable to the metal-bound phosphines $(J(\mathrm{PPt})=3631 \mathrm{~Hz})$, and a singlet at $\delta 24.7$, due to the phosphine oxides. The NMR data point to a plane of symmetry. Furthermore, the presence of three distinct types of methylenic $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2} \mathrm{C}_{6} \mathrm{H}_{2}$ groups is strong indication for proximal chelation, rather than distal co-ordination, such that 1,3 complexation seems not to be favourable in the present case. As for 5, an important downfield shift is observed for a single methylenic $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CHC}_{6} \mathrm{H}_{2}$ hydrogen ( $\delta 7.43, \Delta \delta=3.97 \mathrm{ppm}$ ) whilst the corresponding ${ }^{13} \mathrm{C}$ NMR signal, identified by a ${ }^{13} \mathrm{C}-{ }^{1} \mathrm{H}$ HETCOR experiment, appears far outside of the range expected for a cone conformer ( $\delta 38.88$ ). On the basis of this spectral correspondence, we tentatively assign the conformation of the metallocycle in $\mathbf{8}$ as being similar to that of $\mathbf{5}$.

An alternative method for preventing oligomerization involves complexing the phosphines that remain uncoordinated after the first step. Thus, addition of two equivalents of $[\mathrm{AuCl}(\mathrm{THT})]$ to the product obtained following reaction of one equivalent of $\mathrm{L}^{1}$ with $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$ led to the trinuclear complex 9 (Scheme 4b). Again a single $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}$ signal is strongly deshielded $(\delta(\mathrm{H})=7.35 ; \delta(\mathrm{C})=37.15)$ and can be assigned to the $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ group of the 12 -membered metallacycle. The molecular structure of $\mathbf{9}$ was confirmed by an X-ray diffraction study which will be reported elsewhere. ${ }^{23}$ Surprisingly, reaction of two equivalents of $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$ with $\mathrm{L}^{1}$ did not lead to the expected dinuclear complex but gave rise to polymeric products.
The triphosphine $\mathrm{L}^{2}$ reacts with $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$ in a manner reminescent of the behaviour described for $\mathrm{L}^{1}$; isolation of chelate complex $\mathbf{1 0}$ requiring oxidation of the phosphine remaining unco-ordinated after the first step. Here, the AB system of the axial $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}$ atom assigned to the metallocycle is characterized by $\delta_{\mathrm{A}}=7.20$ and $\delta_{\mathrm{B}}=3.68$. The ${ }^{13} \mathrm{C}$ NMR spectrum displays four $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ signals, three of which lie slightly under the critical value of $\delta 37$ while the fourth appears at $\delta 32.10$. It seems reasonable to assign a partial cone conform-

9

Scheme 4 Construction of chelate complexes involving two proximal phosphines of $L^{1}$.

10
ation to 10. Other important characterizing data are given in the Experimental section. Note, in view of the absence of any symmetry element in complex $\mathbf{1 0}$, the latter exists as a mixture of two enantiomers.

The present study demonstrates that calixarenes bearing two proximal $\mathrm{CH}_{2} \mathrm{PPh}_{2}$ substituents form readily chelate complexes. In particular, $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right]$ reacts with each phosphine-based ligand to give a 12 -membered metallomacrocycle containing the $\mathrm{PtCl}_{2}$ unit. A characteristic feature of these platinum metallomacrocyclic complexes concerns the anomalous chemical shift observed for the axial $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}$ atom belonging to the macrocycle, possibly due to interaction with the lone pairs of the endocyclic oxygen atoms. The metallomacrocycle in complex 5 appears to weaken pre-existing hydrogen bonds compared to those found in free $L^{3}$. Those calixarenes substituted by three or four dangling $\mathrm{CH}_{2} \mathrm{PPh}_{2}$ groups exhibit $\mathrm{P}_{3}$ chelating behaviour. This unique type of triple co-ordination leads to formation of fac-oriented complexes with incoming " $\mathrm{Mo}(\mathrm{CO})_{3}$ " and " $\mathrm{RuCl}_{2}$ " fragments, wherein the metal centre is fixed immediately below the calix cavity.

## Experimental

General experimental details are given as supplementary data (see SUP 57667). The global binding constants $\log \beta_{n}$ were determined by UV-visible spectrophotometric titration in dichloromethane (spectroscopic grade). For these measurements a quartz cell was filled under $\mathrm{N}_{2}$ atmosphere with a solution of complex 4 in dichloromethane $\left(5 \times 10^{-4} \mathrm{M}, 3 \mu \mathrm{~L}\right)$ to which were added multiples of 10 mL of neat acetonitrile solution. The " Ru " : MeCN ratio ranged from 0 to $4: 1$. The spectra were recorded between 190 and 310 nm using a quartz cell ( 1 cm path length) that was thermoregulated at $25 \pm 0.5^{\circ} \mathrm{C}$. The absorbance changes monitored were significant enough to be exploited by multiwavelength numerical treatment based on a Benesi-Hildebrandt type equation (program SPECFIT ${ }^{\oplus 24}$ ), which yielded the desired global binding constants $\log \beta_{n}$.

Compounds $\mathrm{L}^{1,}{ }^{6} \mathrm{~L}^{2}{ }_{\mathrm{ox}},{ }^{6}[\mathrm{AuCl}(\mathrm{THT})],{ }^{25}\left[\mathrm{RuCl}_{2}(\mathrm{DMSO})_{4}\right],{ }^{26}$ $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right],{ }^{27}\left[\mathrm{Mo}(\mathrm{CO})_{3}\left(\mathrm{C}_{7} \mathrm{H}_{8}\right)\right],{ }^{28} \mathrm{Ph}_{2} \mathrm{P}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{O}-\mathrm{SO}_{2} \mathrm{C}_{6} \mathrm{H}_{4}-$ $\mathrm{Me}-p,{ }^{29}$ and $\mathrm{PhSiH}_{3}{ }^{30}$ were prepared according to methods reported in the literature. The di(phosphine oxide) $\mathrm{L}^{3}{ }_{\text {ox }}$ was synthesized according to an improved procedure (see below). The P-methylated version of $\mathrm{L}^{3}$ was prepared according to a procedure similar to that described below for $\mathrm{L}^{3}$, using $\mathrm{Me}_{2} \mathrm{P}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{O}-\mathrm{SO}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}-p$ as alkylating agent and will be fully described elsewhere ( $\delta^{31} \mathrm{P}:-53.8(\mathrm{~s})$ )..$^{31}$

## X-Ray crystallography

Crystal data for $\mathbf{L}_{\text {ox }}^{3} \cdot 2 \mathrm{C}_{70} \mathrm{H}_{78} \mathrm{O}_{6} \mathrm{P}_{2} \cdot \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OC}_{2} \mathrm{H}_{5}, M=2228.82$, triclinic, space group $P \overline{1}$, colourless crystals, $a=14.9993$ (8), $b=15.351(1), c=15.4699(9) \AA, \alpha=102.912(9), \beta=106.361(9)$, $\gamma=103.676(9)^{\circ}, \quad U=3156(1) \AA^{3}, \quad Z=1, \quad D_{\mathrm{c}}=1.17 \mathrm{~g} \mathrm{~cm}^{-3}$, $\mu=0.116 \mathrm{~mm}^{-1}, F(000)=1194$. Data were collected on a Nonius KappaCCD diffractometer (graphite Mo-K $\alpha$ radiation, $0.71073 \AA$ ) at $-100^{\circ} \mathrm{C}$. 22148 Reflections collected $(2.5 \leq \theta \leq$ $\left.26.38^{\circ}\right), 5805$ data with $I>3 \sigma(I)$. The structure was solved
using the Nonius OpenMoleN ${ }^{32}$ package and refined by full matrix least-squares with anisotropic thermal parameters for all non-hydrogen atoms. Final results: $R(F)=0.085, w R(F)=$ 0.109 , goodness of fit $=1.225,712$ parameters, largest difference peak $=1.038$ e $\AA^{-3}$.

Crystal data for complex 5. $2 \mathrm{C}_{70} \mathrm{H}_{156} \mathrm{O}_{12} \mathrm{P}_{4} \mathrm{Pt} \cdot 6 \mathrm{CH}_{2} \mathrm{Cl}_{2} \cdot \mathrm{H}_{2} \mathrm{O}$, $M=3150.30$, orthorhombic, space group $P 2_{1} 2_{1} 2_{1}$, colourless crystals, $a=12.571(1), b=22.5546(3), c=26.4894(3) \AA, \quad V=$ $7510.6(8) \AA^{3}, \quad Z=2, \quad D_{\mathrm{c}}=1.39 \mathrm{~g} \mathrm{~cm}^{-3}, \quad \mu=2.241 \mathrm{~mm}^{-1}$, $F(000)=3212$. Data were collected as above. 50394 Reflections $\left(2.5 \leq \theta \leq 32.39^{\circ}\right), 9230$ data with $I>3 \sigma(I)$. Absolute structure determined refining Flack's $x$ parameter. The structure was solved and refined as above: $R(F)=0.050, w R(F)=0.068$, goodness of fit $=1.028,824$ parameters, largest difference peak $=1.416 \mathrm{e}^{-3}$.

## Syntheses

5,11,17,23-Tetra-tert-butyl-25,26,27-tris(diphenylphosphino-methoxy)-28-methoxycalix[4]arene $\mathbf{L}^{2}$. A suspension of compound $\mathrm{L}^{2}{ }_{\mathrm{ox}}(6.100 \mathrm{~g}, 4.67 \mathrm{mmol})$ in phenylsilane $(7.00 \mathrm{~mL}, 97.80$ mmol ) was heated at $90-100^{\circ} \mathrm{C}$ for 12 d . After evaporation of the solvent in vacuo the residue was subjected to flash chromatography using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ as eluent. The fraction corresponding to $R_{\mathrm{f}}=0.67\left(\mathrm{SiO}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}-\right.$ hexane, $1: 1$, v/v $)$ was concentrated to $c a .30 \mathrm{~mL}$. Precipitation with MeOH yielded compound $\mathrm{L}^{2}$ as a colourless powder. Yield: $5.288 \mathrm{~g}, 90 \% ; \mathrm{mp} 152-154{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR ( $300 \mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CDCl}_{3}$ ): $\delta 7.50-7.26\left(30 \mathrm{H}, \mathrm{PPh}_{2}\right), 7.06$ and $6.90(2 \mathrm{~s}, 2 \mathrm{H}$ each, $m$ - H of aryl), 6.42 and 6.38 ( AB quartet, ${ }^{4} J \approx 2,2 \mathrm{H}$ each, $m$-H of aryl), 5.48 (broad s, $\left.2 \mathrm{H}, \mathrm{PCH}_{2} \mathrm{O}\right), 4.66$ and 4.62 (ABX spin system with $\mathrm{X}=\mathrm{P},{ }^{2} J=12,{ }^{2} J_{\mathrm{AX}}=3$, ${ }^{2} J_{\mathrm{BX}}=2,2 \mathrm{H}$ each, $\mathrm{PCH}_{2} \mathrm{O}$ adjacent to methoxy), 4.51 and 3.01 (AB quartet, ${ }^{2} J=13,2 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 4.16 and $3.06(\mathrm{AB}$ quartet, ${ }^{2} J=13 \mathrm{~Hz}, 2 \mathrm{H}$ each, $\left.\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}\right), 3.33\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right)$, 1.34, 1.32 and $0.83\left(3 \mathrm{~s}, 9 \mathrm{H}+9 \mathrm{H}+18 \mathrm{H}\right.$, tert-butyl). ${ }^{13} \mathrm{C}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $50 \mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CDCl}_{3}$ ): $\delta 155.68-131.47$ (quat. aryl C), 133.81-124.31 (aryl CH), $77.10\left(\mathrm{~d}, J_{\mathrm{PC}} \approx 10, \mathrm{PCH}_{2} \mathrm{O}\right), 75.12(\mathrm{~d}$, $\left.J_{\mathrm{PC}} \approx 20 \mathrm{~Hz}, \mathrm{PCH}_{2} \mathrm{O}\right), 60.26\left(\mathrm{~s}, \mathrm{OCH}_{3}\right), 34.10$ and $33.60(3 \mathrm{~s}$, $\left.C\left(\mathrm{CH}_{3}\right)_{3}\right), 32.61\left(\mathrm{~s}, \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}\right), 31.76$ and $31.15\left(\mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right)$ (one $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ signal is probably overlapping with a tert-butyl signal). ${ }^{31} \mathrm{P}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $121 \mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CDCl}_{3}$ ): $\delta-17.3$ (s, 2P) and $-18.6(\mathrm{~s}, 1 \mathrm{P})$. Found: C, $80.11 ; \mathrm{H}, 7.35$. Calc. for $\mathrm{C}_{84} \mathrm{H}_{91}{ }^{-}$ $\mathrm{O}_{4} \mathrm{P}_{3}: \mathrm{C}, 80.23 ; \mathrm{H}, 7.29 \%$.
(Improved preparation of) 5,11,17,23-tetra-tert-butyl-25,26-bis(diphenylphosphinoylmethoxy)-27,28-dihydroxycalix[4]arene $\mathbf{L}^{\mathbf{3}}{ }_{\mathbf{o x}}$. To a suspension of p-tert-butylcalix[4]arene $(5.000 \mathrm{~g}, 7.70$ mmol) in DMF ( 200 mL ), cooled at $0^{\circ} \mathrm{C}$, was added in portions $\mathrm{NaH}(0.647 \mathrm{~g}, 26.97 \mathrm{mmol})$. After stirring for $1.5 \mathrm{~h}, \mathrm{Ph}_{2} \mathrm{P}(\mathrm{O})-$ $\mathrm{CH}_{2} \mathrm{O}-\mathrm{SO}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}-p(8.920 \mathrm{~g}, 23.10 \mathrm{mmol})$ was added and the solution further stirred for 2 h at $0^{\circ} \mathrm{C}$. After 24 h the excess of NaH was decomposed with $\mathrm{MeOH}(10 \mathrm{~mL})$, then the solvent was removed in vacuo. The residue was taken up in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(250$ $\mathrm{mL})$ and washed with $1 \mathrm{M} \mathrm{HCl}(80 \mathrm{~mL})$, then with water $(2 \times 100 \mathrm{~mL})$. The organic layer was dried with $\mathrm{MgSO}_{4}$ and evaporated to dryness to afford a solid which was purified by flash column chromatography using ethyl acetate-hexane ( $1: 1$, $\mathrm{v} / \mathrm{v})$ as eluent. The fraction eluting first $\left(\mathrm{SiO}_{2}, R_{\mathrm{f}}=0.79\right.$, yield $10 \%$ ), was discarded. Compound $\mathrm{L}^{3}{ }_{\text {ox }}$ which is the second compound migrating on the column $\left(R_{\mathrm{f}}=0.55\right)$ was obtained as an analytically pure colourless solid ( $5.475 \mathrm{~g}, 66 \%$ ). Spectroscopic data have been published previously. ${ }^{6}$

## 5,11,17,23-Tetra-tert-butyl-25,26-bis(diphenylphosphino-

 methoxy)-27,28-dihydroxycalix[4]arene $L^{3}$. A suspension of compound $\mathrm{L}^{3}{ }_{\text {ox }}(6.200 \mathrm{~g}, 5.75 \mathrm{mmol})$ in toluene $(120 \mathrm{~mL})$ washeated at $90-100^{\circ} \mathrm{C}$ in the presence of phenylsilane $(2.1 \mathrm{~mL}$, 28.75 mmol ) for 7 days. After evaporation of the solvent in vacuo the residue was subjected to flash chromatography using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$-hexane ( $1: 1, \mathrm{v} / \mathrm{v}$ ) as eluent. The fraction obtained with $R_{\mathrm{f}}=0.23\left(\mathrm{SiO}_{2}\right)$ was concentrated to $c a .40 \mathrm{~mL}$, and addition of MeOH yielded compound $\mathrm{L}^{3}$ as a colourless powder. Yield: $5.951 \mathrm{~g}, 99 \%$; mp $201-203{ }^{\circ} \mathrm{C}$. IR ( KBr ) ( $\tilde{v}_{\text {max }} / \mathrm{cm}^{-1}$ ): 3362 br $(\mathrm{OH}) .{ }^{1} \mathrm{H}$ NMR $\left(300 \mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CDCl}_{3}\right): \delta 8.91(\mathrm{~s}, 2 \mathrm{H}, \mathrm{OH})$, 7.49-7.32 ( $20 \mathrm{H}, \mathrm{PPh}_{2}$ ), 7.01 and $6.96\left(\mathrm{AB}\right.$ system, ${ }^{4} J=3,2 \mathrm{H}$ each, $m$-H of aryl), 6.93 and $6.86\left(\mathrm{AB}\right.$ system, ${ }^{4} J=3,2 \mathrm{H}$ each, $m-\mathrm{H}$ of aryl), 5.19 and $4.93\left(\mathrm{ABX}\right.$ system with $\mathrm{X}=\mathrm{P},{ }^{2} J_{\mathrm{AB}}=12$, ${ }^{2} J_{\mathrm{AX}}=2,{ }^{2} J_{\mathrm{BX}}=3,2 \mathrm{H}$ each, $\left.\mathrm{PCH}_{2} \mathrm{O}\right), 4.59$ and $3.20(\mathrm{AB}$ quartet, ${ }^{2} J=13,1 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 4.48 and 3.27 (AB quartet, ${ }^{2} J=13,2 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 4.15 and 3.32 (AB quartet, ${ }^{2} J=14 \mathrm{~Hz}, 1 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 1.22 and 1.12 ( $2 \mathrm{~s}, 18 \mathrm{H}$ each, tert-butyl). ${ }^{13} \mathrm{C}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(50 \mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CDCl}_{3}\right): \delta 152.81-$ 125.78 (quat. aryl C), 133.58-125.29 (aryl CH), 77.96 (broad s, $\left.\mathrm{PCH}_{2} \mathrm{O}\right), 34.06$ and $33.94\left(2 \mathrm{~s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right), 33.26,32.84$ and 32.01 (3s, $\left.\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}\right), 31.63$ and $31.33\left(2 \mathrm{~s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right) \cdot{ }^{31} \mathrm{P}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $121 \mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CDCl}_{3}$ ): $\delta-20.2$ (s). 1 H each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 6.51 and 5.30 (broad AB quartet, ${ }^{2} J_{\mathrm{AB}}=13,2 \mathrm{H}$ each, $\mathrm{PtPCH}_{2} \mathrm{O}$ ), 5.14 and 4.68 ( ABX system with $\mathrm{X}=\mathrm{P},{ }^{2} J_{\mathrm{AB}}=13,{ }^{2} J_{\mathrm{AX}}=2,{ }^{2} J_{\mathrm{BX}}=1,2 \mathrm{H}$ each, $\mathrm{PCH}_{2} \mathrm{O}$ ), 4.86 and 3.00 (AB quartet, ${ }^{2} J=13,1 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 4.75 and 2.86 (AB quartet, ${ }^{2} J=13 \mathrm{~Hz}, 2 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 1.24 and $1.05\left(2 \mathrm{~s}, 18 \mathrm{H}+18 \mathrm{H}\right.$, tert-butyl). ${ }^{13} \mathrm{C}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( 50 $\mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ): $\delta 154.46$ and 153.91 ( 2 s , quat. aryl C-O), 146.71-132.81 (quat. aryl C), 134.50-125.61 (aryl CH), 73.72 $\left(\mathrm{d}, J_{\mathrm{PC}}=78, \mathrm{PCH}_{2} \mathrm{O}\right), 73.83\left(\mathrm{~d}, J_{\mathrm{PC}}=48 \mathrm{~Hz}, \mathrm{PCH}_{2} \mathrm{O}\right), 38.88(\mathrm{~s}$, $\left.\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}\right), 34.36$ and $34.21\left(2 \mathrm{~s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right), 31.75(\mathrm{~s}, 2 \times$ $\left.\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}\right), 31.53$ and $31.52\left(2 \mathrm{~s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right) .{ }^{31} \mathrm{P}-\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}$ ( $121 \mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ): $\delta 24.7$ (s), 8.6 (s with Pt satellites, $\left.J_{\text {P-Pt }}=3631 \mathrm{~Hz}\right)$. FAB mass spectrum: $m / z 1739\left([M+\mathrm{H}]^{+}\right.$, 3), $1703\left([M-\mathrm{Cl}]^{+}, 65\right)$ and $1667\left([M-2 \mathrm{Cl}]^{2+}, 50 \%\right)$. Found: C, $66.11 ; \mathrm{H}, 5.82$. Calc. for $\mathrm{C}_{96} \mathrm{H}_{100} \mathrm{Cl}_{2} \mathrm{O}_{6} \mathrm{P}_{4} \mathrm{Pt}: \mathrm{C}, 66.28 ; \mathrm{H}$, 5.79\%.

Tetrachloro\{5,11,17,23-tetra-tert-butyl-25,26,27,28-tetrakis-(diphenylphosphinomethoxy)calix[4]arene-1 $\kappa^{2} P, P^{\prime} ; \quad 2 \kappa P^{\prime \prime}$, $\left.\mathbf{3 \kappa} \boldsymbol{P}^{\prime \prime \prime}\right\}$ digold(I)platinum(II) 9. To a solution of compound $\mathrm{L}^{1}$ $(0.100 \mathrm{~g}, 0.07 \mathrm{mmol})$ in THF ( 5 mL ) was added a solution of $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right](0.026 \mathrm{~g}, 0.07 \mathrm{mmol})$ in THF ( 5 mL ). After 1 h a solution of $[\mathrm{AuCl}(\mathrm{THT})](0.044 \mathrm{~g}, 0.14 \mathrm{mmol})$ in THF $(5 \mathrm{~mL})$ was added. The solution was filtered over a bed of Celite after 10 min , and evaporated to dryness in vacuo. The residue was subjected to flash chromatography using $\mathrm{MeOH}-\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (4:96, $\mathrm{v} / \mathrm{v})$ as eluent. The fraction with $R_{\mathrm{f}}=0.42\left(\mathrm{SiO}_{2}\right)$ was recrystallized from ethyl acetate-hexane ( $1: 1, \mathrm{v} / \mathrm{v}$ ) precipitating complex 9 as a colourless solid. Yield: $0.092 \mathrm{~g}, 88 \% ; \mathrm{mp} 250^{\circ} \mathrm{C}$ (decomp.). ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CDCl}_{3}$ ): $\delta 7.81-6.40(\mathrm{~m}$, $48 \mathrm{H}, m$ - H of aryl $+\mathrm{PPh}_{2}$ ), 7.35 and 3.63 ( AB quartet, ${ }^{2} J_{\mathrm{AB}}=13,1 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 5.83 and 4.85 ( AB quartet, ${ }^{2} J_{\mathrm{AB}}=13,2 \mathrm{H}$ each, $\left.\mathrm{PCH}_{2} \mathrm{O}\right), 5.12$ and $4.90(\mathrm{ABX}$ system with $\mathrm{X}=\mathrm{P},{ }^{2} J_{\mathrm{AB}}=13,{ }^{2} J_{\mathrm{AX}}=0,{ }^{2} J_{\mathrm{BX}}=4,2 \mathrm{H}$ each, $\mathrm{PCH}_{2} \mathrm{O}$ ), 4.98 and 3.07 (AB quartet, ${ }^{2} J=13,1 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 4.15 and 3.35 (AB quartet, ${ }^{2} J=13 \mathrm{~Hz}, 2 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 1.21 and $0.94\left(2 \mathrm{~s}, 18 \mathrm{H}+18 \mathrm{H}\right.$, tert-butyl). ${ }^{13} \mathrm{C}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( 50 $\mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CDCl}_{3}$ ): $\delta 153.23$ and 151.77 (2s, quat. aryl C-O), 146.55-125.09 (quat. aryl C), 134.41-125.76 (aryl CH), $75.02\left(\mathrm{~d}, J_{\mathrm{PC}}=64, \mathrm{PCH}_{2} \mathrm{O}\right), 73.73\left(\mathrm{~d}, J_{\mathrm{PC}}=40 \mathrm{~Hz}, \mathrm{PCH}_{2} \mathrm{O}\right)$, $37.15\left(\mathrm{~s}, \mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}\right), 34.09$ and $33.92\left(2 \mathrm{~s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right), 31.86$ (s, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ) and $31.45\left(\mathrm{~s}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right) .{ }^{31} \mathrm{P}-\left\{{ }^{1} \mathrm{H}\right\}$ NMR $(121 \mathrm{MHz}$, $293 \mathrm{~K}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$ ): $\delta 21.9$ (s) and 8.1 (s with Pt satellites, $J_{\text {P-Pt }}=$ 3634 Hz ). Found: C, 53.16; H, 4.56. Calc. for $\mathrm{C}_{96} \mathrm{H}_{100} \mathrm{Au}_{2}-$ $\mathrm{Cl}_{4} \mathrm{O}_{4} \mathrm{P}_{4} \mathrm{Pt}: \mathrm{C}, 53.07 ; \mathrm{H}, 4.64 \%$.
cis-Dichloro $5,11,17,23$-tetra-tert-butyl-25,26-bis(diphenyl-phosphinomethoxy)-27-(diphenylphosphinoylmethoxy)-28-methoxycalix[4]arene- $P, P^{\prime}$ \}platinum(II) 10 and its enantiomer. To a solution of $\mathrm{L}^{2}(0.150 \mathrm{~g}, 0.12 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \mathrm{~mL})$ was added a solution of $\left[\mathrm{PtCl}_{2}(\mathrm{COD})\right](0.045 \mathrm{~g}, 0.12 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \mathrm{~mL})$. After 1 h an excess of $\mathrm{H}_{2} \mathrm{O}_{2}$-urea adduct $(0.050 \mathrm{~g})$ was added, and the solution stirred vigorously for 1 h . The solution was filtered and evaporated to dryness in vacuo. The residue was subjected to flash chromatography using ethyl acetate-hexane ( $65: 35, \mathrm{v} / \mathrm{v}$ ) as eluent. The fraction with $R_{\mathrm{f}}=0.58\left(\mathrm{SiO}_{2}\right)$ was recrystallized from ethyl acetate-hexane ( $1: 1, \mathrm{v} / \mathrm{v}$ ) affording the complex rac-10 as a colourless solid. Yield: $0.101 \mathrm{~g}, 68 \% ; \mathrm{mp}>250^{\circ} \mathrm{C}$ (decomp.). IR (KBr) ( $\tilde{\nu}_{\text {max }} /$ $\mathrm{cm}^{-1}$ ): 1192s ( $\mathrm{P}=\mathrm{O}$, tentative assignment). ${ }^{1} \mathrm{H}$ NMR ( 500 $\left.\mathrm{MHz}, 293 \mathrm{~K}, \mathrm{CD}_{2} \mathrm{Cl}_{2}\right): \delta 8.05-7.95$ and 7.56-6.56 (m, 38 H , $m$-H of aryl $+\mathrm{PPh}_{2}$ ), 7.20 and 3.68 ( AB quartet, ${ }^{2} J=13,1 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 6.26 and 5.24 ( ABX system with $\mathrm{X}=\mathrm{P}$, ${ }^{2} J_{\mathrm{AB}}=11,{ }^{2} J_{\mathrm{AX}}=0,{ }^{2} J_{\mathrm{BX}}=4,1 \mathrm{H}$ each, $\left.\mathrm{PCH}_{2} \mathrm{O}\right), 4.75$ and 2.93 (AB quartet, ${ }^{2} J=13,1 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 4.64 and 4.47 (ABX system with $\mathrm{X}=\mathrm{P},{ }^{2} J_{\mathrm{AB}}=13,{ }^{2} J_{\mathrm{AX}}=3,{ }^{2} J_{\mathrm{BX}}=4,1 \mathrm{H}$ each, $\left.\mathrm{PCH}_{2} \mathrm{O}\right), 4.35$ and $3.88\left(\mathrm{ABX}\right.$ system with $\mathrm{X}=\mathrm{P},{ }^{2} J_{\mathrm{AB}}=10$, ${ }^{2} J_{\mathrm{AX}}=3,{ }^{2} J_{\mathrm{BX}}=0,1 \mathrm{H}$ each, $\left.\mathrm{PCH}_{2} \mathrm{O}\right), 4.32$ and $3.62(\mathrm{AB}$ quartet, ${ }^{2} J=13,1 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 3.67 and 3.53 (AB quartet, ${ }^{2} J=13 \mathrm{~Hz}, 1 \mathrm{H}$ each, $\mathrm{C}_{6} \mathrm{H}_{2} \mathrm{CH}_{2}$ ), 1.34, 1.25, 1.11 and
