# Copolymerization of cyclohexene oxide and carbon dioxide using (salen)Co(III) complexes: synthesis and characterization of syndiotactic poly(cyclohexene carbonate) $\dagger$ 

Claire T. Cohen, Christophe M. Thomas, Kathryn L. Peretti, Emil B. Lobkovsky and Geoffrey W. Coates*

Received 15th September 2005, Accepted 2nd November 2005<br>First published as an Advance Article on the web 24th November 2005<br>DOI: 10.1039/b513107c

Synthetic routes to a series of new (salen) $\operatorname{CoX}$ (salen $=N, N^{\prime}$-bis(salicylidene)-1,2-diaminoalkane; $\mathrm{X}=$ halide or carboxylate) species are described and the X-ray crystal structures of two (salen-1)CoX (salen-1 $=N, N^{\prime}$-bis(3,5-di-tert-butylsalicylidene)-1,2-diaminocyclohexane; $\mathrm{X}=\mathrm{Cl}, \mathrm{I}$ ) complexes are presented. $(R, R)$-(salen-1) $\mathrm{CoX}\left(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{OAc}\right.$, pentafluorobenzoate $\left.\left(\mathrm{OBzF}_{5}\right)\right)$ catalysts are active for the copolymerization of cyclohexene oxide $(\mathrm{CHO})$ and $\mathrm{CO}_{2}$, yielding syndiotactic poly(cyclohexene carbonate) (PCHC), a previously unreported PCHC microstructure. Variation of the salen ligand and reaction conditions, as well as the inclusion of $[\mathrm{PPN}] \mathrm{Cl}([\mathrm{PPN}] \mathrm{Cl}=$ bis(triphenylphosphine)iminium chloride) cocatalysts, has dramatic effects on the polymerization rate and the resultant PCHC tacticity. Catalysts rac-(salen-6)CoX (salen-6 $=N, N^{\prime}$-bis(3,5-di-tert-butylsalicylidene)-1,2-diaminopropane; $\mathrm{X}=$ $\mathrm{Br}, \mathrm{OBzF}_{5}$ ) have high activities for $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization, yielding syndiotactic PCHCs with up to $81 \% r$-centered tetrads. Using Bernoullian statistical methods, PCHC tetrad and triad sequences were assigned in the ${ }^{13} \mathrm{C}$ NMR spectra of these polymers in the carbonyl and methylene regions, respectively.

## Introduction

The correlation between a polymer's main-chain stereochemistry and its physical properties has stimulated many research efforts in the field of stereospecific polymerization. Ordered polymer architectures, where sequential stereocenters are of the same (isotactic) or alternating (syndiotactic) relative configuration are generally more crystalline than their atactic counterparts. Although heterogeneous catalysts can be used to control polymer microstructure in some cases, homogeneous systems are more commonly employed for this purpose. Notably, these discrete polymerization catalysts can be designed at the molecular level, providing for a tunable active site.
The alternating copolymerization of epoxides and $\mathrm{CO}_{2}$ to generate biodegradable polycarbonates has been a subject of much interest as $\mathrm{CO}_{2}$ is a readily available, inexpensive, non-toxic and nonflammable reagent (Scheme 1). ${ }^{1}$ The first epoxide $/ \mathrm{CO}_{2}$ copolymerization was achieved by Inoue using $\mathrm{ZnEt}_{2} / \mathrm{H}_{2} \mathrm{O}$ catalysts in 1969. ${ }^{2}$ Following this discovery, several other heterogeneous systems were developed for this transformation; however, catalyst activities remained low with little control of polymer microstructure. To improve catalyst performance, recent research has focused on single-site epoxide/ $\mathrm{CO}_{2}$ copolymerization catalysts. ${ }^{1,3-18}$ To date, these homogeneous systems have achieved high activities for epoxide $/ \mathrm{CO}_{2}$ copolymerization and in some cases stereo- and/or regiospecific monomer enchainment. ${ }^{5,6,11-18}$
The asymmetric alternating copolymerization of cyclohexene oxide ( CHO ) and $\mathrm{CO}_{2}$ has been demonstrated first by Nozaki using $\mathrm{ZnEt}_{2}$ /chiral amino alcohol catalysts and later by our group

[^0]

Scheme 1 Copolymerization of epoxides and $\mathrm{CO}_{2}$ to yield polycarbonates.
using hybrid imine-oxazoline zinc-based catalysts (Fig. 1). ${ }^{11-14,18}$ In each system, isotactic poly(cyclohexene carbonate) (PCHC) with an enantiomeric excess (ee) $\sim 70 \%$ is obtained. These isotactic PCHCs have been structurally characterized by ${ }^{13} \mathrm{C}$ NMR spectroscopy using both model compounds and statistical methods. ${ }^{14,19}$ These systems show that chiral ligands allow the generation of isotactic PCHC, consistent with a site-control copolymerization mechanism. ${ }^{11-14}$

Fig. 1 Catalysts for the isospecific copolymerization of cyclohexene oxide and $\mathrm{CO}_{2} ; \mathrm{R}^{1}=\mathrm{Me}, \mathrm{CF}_{3}$, or ${ }^{\mathrm{i}} \mathrm{Pr} ; \mathrm{R}^{2}=(R)-\mathrm{Ph},(S)^{-} \mathrm{Pr}$, or $(S)-{ }^{-} \mathrm{Bu} ; \mathrm{R}^{3}=\mathrm{Et}$ or ${ }^{i} \mathrm{Pr}$.

Recently we reported that (salen-1)CoX complexes (salen-1 = $N, N^{\prime}$-bis(3,5-di-tert-butylsalicylidene)-1,2-diaminocyclohexane; $\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{OAc}$, pentafluorobenzoate $\left(\mathrm{OBzF}_{5}\right)$; Fig. 2) are highly active catalysts for the copolymerization of propylene oxide (PO) and $\mathrm{CO}_{2}$ to yield poly(propylene carbonate) (PPC) with no detectable propylene carbonate byproduct. $5,6,17$ Using these catalyst systems, we observed a variety of PPC microstructures, in which the regio- and stereochemical composition of the resultant

Fig. 2 (salen-1)CoX catalysts for the copolymerization of epoxides and $\mathrm{CO}_{2}(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}$, acetate, pentafluorobenzoate).

PPC was dependent on the relative stereochemistry of the catalyst and monomer. Furthermore, through the addition of bulky, organic ionic cocatalysts to these systems unprecedented activities were observed, while maintaining excellent regioselectivity. ${ }^{6,17 b}$ Based on our success with (salen-1)CoX catalysts for $\mathrm{PO} / \mathrm{CO}_{2}$ copolymerization, we likewise applied these systems to $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization, with a focus on maximization of catalyst activity and control of product PCHC microstructure.
Herein, we report the synthesis of a series of (salen)CoX (salen = $N, N^{\prime}$-bis(salicylidene)-1,2-diaminoalkane; $\mathrm{X}=$ halide or carboxylate) complexes that are active for $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization, and we present the X-ray crystal structures of $(R, R)$-(salen-1) CoCl and rac -(salen-1)CoI. In addition, we address the effects of the salen ligand and catalyst axial ligand/initiator (X) used, the reaction conditions, and the inclusion of $[\mathrm{PPN}] \mathrm{Cl}([\mathrm{PPN}] \mathrm{Cl}=$ bis(triphenylphosphine)iminium chloride) cocatalysts on activity and stereospecificity for the copolymerization. With these catalysts, we obtain PCHC with various stereochemical architectures, including syndiotactic PCHC, a previously unreported PCHC microstructure. Using Bernoullian statistical methods, we assign PCHC tetrad and triad sequences for the ${ }^{13} \mathrm{C}$ NMR spectra of these polymers in the carbonyl and methylene regions, respectively.

## Results and discussion

## Catalyst synthesis

Oxidation of commercially available $(R, R)$-(salen-1)Co readily occurs in the presence of organic acids to yield the corresponding $(R, R)$-(salen-1)CoOAc, ${ }^{20}(R, R)$-(salen-1)CoOTs (OTs $=$ $p$-tolylsulfonate), ${ }^{21}$ and $(R, R)$-(salen-1) $\mathrm{CoOBzF}_{5} .{ }^{6}(R, R)$-(salen1) CoOTs can be further modified through metathesis reactions with the desired NaX salt, affording $(R, R)$-(salen-1) $\mathrm{CoX}(\mathrm{X}=\mathrm{Cl}$, $\mathrm{Br}, \mathrm{I}) .{ }^{6,21}$ Rac-(salen-1)CoX catalysts were prepared by a $50: 50$ mixture of $(R, R)$-(salen-1)Co and ( $S, S$ )-(salen-1)Co. A variety of other (salen)CoX complexes were synthesized, starting with an aldehyde/diamine Schiff-base condensation to generate the desired salen-ligand, followed by metallation with cobalt(II) acetate tetrahydrate and subsequent oxidation reactions. The complete series of (salen)CoX complexes used in this study is given in Fig. 3. Although the majority of the (salen)CoX complexes were obtained as powders, in limited cases X-ray quality crystals were obtained from slow evaporation of benzene $((R, R)-($ salen -1$) \mathrm{CoCl})$ or by slow evaporation of a methylene chloride/hexane (1:1) solution (rac-(salen-1)CoI). The X-ray crystal structures of $(R, R)$-(salen1) CoCl and the $(R, R)$-(salen-1) CoI component of rac-(salen1)CoI with selected bond angles and bond lengths are shown in Fig. 4 and 5, respectively. In both cases, the (salen-1)CoX complex is pseudo square-pyramidal with the Co located slightly above the plane of the salen ligand in the direction of the axial ligand.

Alternating copolymerization of cyclohexene oxide and carbon dioxide with (salen)CoX catalysts. The high $\mathrm{PO} / \mathrm{CO}_{2}$ copolymerization activities and selectivities observed with catalysts $(R, R)$ -(salen-1) $\operatorname{CoX}\left(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{OAc}, \mathrm{OBzF}_{5}\right)$ led us to investigate
these systems for $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization. ${ }^{5,6}$ Initially, we employed high $\mathrm{CO}_{2}$ pressures ( 54.4 atm ) with a $[\mathrm{CHO}]$ : [Co] loading of $500: 1$ using a series of catalyst axial ligands/initiators (X). To our surprise, the ${ }^{13} \mathrm{C}$ NMR spectra of the resultant PCHCs were unlike those previously reported. Based on prior PCHC ${ }^{13} \mathrm{C}$ NMR assignments of the carbonyl region, ${ }^{13,14,19,22}$ our PCHCs revealed a strong contribution correlating to $r$-centered tetrads, indicative of syndiotactic PCHC (Fig. 6, see following discussion and Fig. 8). Furthermore, we detected up to $81 \% r$ centered tetrads in our PCHCs depending on the catalyst's ligand structure. ${ }^{22}$ To the best of our knowledge, these are the first $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization catalysts to produce syndiotactic PCHC.

Fig. 6 Carbonyl region of the ${ }^{13} \mathrm{C}$ NMR spectrum $\left(\mathrm{CDCl}_{3}, 125 \mathrm{MHz}\right)$ of poly(cyclcohexene carbonate) generated using catalyst $(R, R)$-(salen-1) CoI.

The $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization data for $(R, R)$-(salen-1) CoX $\left(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{OAc}, \mathrm{OBzF}_{5}\right)$ catalysts are listed in Table 1. While most of the catalyst activities were quite similar (entries $1-3,5)$, when acetate was used as an initiating group, catalyst activity decreases substantially (entry 4). Overall, $(R, R)$-(salen1)CoX catalysts had turnover frequencies (TOF)s $\leq 16 \mathrm{~h}^{-1}$ for $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization. As much higher activities were observed with these catalyst systems for $\mathrm{PO} / \mathrm{CO}_{2}$ copolymerization under comparable reaction conditions, ${ }^{6}$ we suspect that reaction rates are hindered by the more sterically bulky, less reactive CHO monomer. Generally, variation of the axial ligand/initiator had little influence on the syndiotacticity of the resultant PCHC, however, when iodide was used, the resultant PCHC was exceptionally syndiotactic. Furthermore, the role of the iodide axial ligand in the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization is under current investigation.

In all cases, the PCHCs we obtained exhibit $M_{\mathrm{n}}$ values lower than the corresponding theoretical values despite the absence of
chain transfer agents. Notably, this was not observed with these catalyst systems for $\mathrm{PO} / \mathrm{CO}_{2}$ copolymerization under comparable reaction conditions. ${ }^{6}$ As such, we are currently looking into the possibilities of chain transfer to monomer or trace water and/or the formation of cyclic polymer. The syndiotactic PCHCs we obtain are amorphous, with no observable melting point transition. In an effort to obtain more crystalline PCHC we are presently synthesizing syndiotactic PCHCs with higher $M_{\mathrm{n}}$ values.

It has been shown previously that minor alterations of the salen ligands in their chromium-, cobalt- or aluminium-based complexes have dramatic effects on epoxide/ $\mathrm{CO}_{2}$ copolymerization activity. ${ }^{6,8-10,16,17}$ To explore the relationship of the structural features of the salen ligand to catalyst performance in our systems, we synthesized a diverse series of (salen)CoX complexes (Fig. 3) for use in $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization. Table 2 lists the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization data for a series of (salen) CoBr catalysts, in which systematic changes in the diimine backbone have been employed in order to study their impact on polymerization behavior. In all cases a [CHO]: [Co] loading of $500: 1$ was applied while using high $\mathrm{CO}_{2}$ pressures ( 54.4 atm ). Catalyst $(R, R)$ -(salen-1) CoBr produces PCHC with $66 \% r$-centered tetrads and a TOF of $16 \mathrm{~h}^{-1}$ (entry 1). Alternatively, its racemic analogue (rac-(salen-1) CoBr ) is more syndiospecific, generating PCHC with $78 \% r$-centered tetrads (entry 2 ). Increasing the steric bulk on the catalyst backbone $((R, R)$-(salen-2)CoBr) reduces the TOF to $2 \mathrm{~h}^{-1}$ and yields PCHC with only $61 \% r$-centered tetrads (entry 3). Complex (salen-3)CoBr, with a phenylene diimine backbone, has very low activity for the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization with only trace PCHC observed after 20 h (entry 4). Although the similar complex (salen-3)CoOAc is highly active for isospecific PO homopolymerization, ${ }^{23}$ (salen-3)CoBr does not catalyze this transformation. The $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization rate is also reduced compared to that observed with $(R, R)$-(salen-1) CoBr when a 1,1-dimethyl substituted backbone is used ((salen-4)CoBr) (entry 5). However, decreasing the steric bulk with (salen-5) CoBr or rac-(salen-6) CoBr results in a substantial increase in catalyst activity while maintaining the high syndiospecificity initially observed (entries 6 and 7). In fact, complex rac-(salen-6) CoBr produces PCHC with $81 \% r$-centered tetrads, which is the greatest syndiotacticity that we have observed in PCHC formation to date. Interestingly, use of the most active catalysts ((salen-5)CoBr or rac-(salen-6)CoBr) results in very high conversions even though the polymerization is run in neat CHO (entries 6 and 7). We suspect that at $54.4 \mathrm{~atm}, \mathrm{CO}_{2}$ plays a role as a solvent and/or lowers the viscosity of the reaction mixture such that the polymerization can proceed to high PCHC yields. Finally, based on a shorter

${ }^{a}$ Copolymerizations run in neat cyclohexene oxide $(\mathrm{CHO})$ at $22^{\circ} \mathrm{C}$ with $[\mathrm{CHO}]:[\mathrm{Co}]=500: 1$ at 54.4 atm of $\mathrm{CO}_{2}$. In all cases, cyclohexene carbonate byproduct is not observed and product poly(cyclohexene carbonate)s ( PCHC )s have $\geq 96 \%$ carbonate linkages as determined by ${ }^{1} \mathrm{H}$ NMR spectroscopy $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right) .{ }^{b}$ Based on isolated PCHC yield. ${ }^{c}$ Turnover frequency $=\mathrm{molCHO}(\mathrm{mol} \mathrm{Co})^{-1} \mathrm{~h}^{-1}$. ${ }^{d}$ Determined by gel permeation chromatography calibrated with polystyrene standards in tetrahydrofuran at $40{ }^{\circ} \mathrm{C}$. ${ }^{e}$ Determined by ${ }^{13} \mathrm{C} \mathrm{NMR}$ spectroscopy ( $\mathrm{CDCl}{ }_{3}, 125 \mathrm{MHz}$ ).
reaction time, catalyst rac-(salen-6) CoBr exhibited high activity (TOF $=98 \mathrm{~h}^{-1}$ ) (entry 8). In general, we found that for (salen) CoBr catalysts, the highest activity and syndiospecificity were both achieved by using a racemic ligand backbone with minimal steric hindrance.

Using the highly active rac-propyldiimine ligand backbone, we investigated the influence of the phenolate ortho and para substituents on (salen) CoX catalyzed $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization (Table 3). It is notable that the catalyst axial ligand $\mathrm{X}=\mathrm{OBzF}_{5}$ was used in this study (instead of $\mathrm{X}=\mathrm{Br}$ as above) because the complexes rac -(salen-8) CoBr and rac -(salen-9) CoBr proved too soluble to purify by washing with pentane. The $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization using catalyst rac-(salen-6) $\mathrm{CoOBzF}_{5}$ is highly active with a TOF of $93 \mathrm{~h}^{-1}$ yielding PCHC with $76 \% r$-centered tetrads (entry 1). These values are similar to those observed with the analogous $\mathrm{X}=\mathrm{Br}$ complex (Table 2, entry 8 ). Increasing the steric bulk of the phenolate ortho and para substituents using rac-(salen-7) $\mathrm{CoOBzF}_{5}$ is detrimental, decreasing catalyst activity to a TOF of $5 \mathrm{~h}^{-1}$ and reducing syndiotacticity to $65 \%$ (entry 2). Alternatively, using catalyst rac -(salen-8) $\mathrm{CoOBzF}_{5}$ where the steric bulk of the ortho and para positions is virtually nonexistent results in a complete loss in stereospecificity yielding atactic PCHC (entry 3). In the intermediate cases which incorporating tert-butyl groups in the ortho positions while varying the para positions of the phenolate to either H or $\mathrm{Br}\left(\mathrm{rac}\right.$-(salen-9) $\mathrm{CoOBzF}_{5}$ or rac-(salen10) $\mathrm{CoOBzF}_{5}$, respectively) catalyst activity and syndiospecificity are decreased (entries 4 and 5). Largely, the salen ligand with tertbutyl groups in both the ortho and para positions of the phenolate moiety provides the ideal steric bulk for use in the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerizations, giving high activity and syndiospecificity.

As enantiomerically pure, racemic and achiral (salen)CoX catalysts are all syndiospecific for $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization, we suspect that monomer enchainment proceeds by a chain-end control mechanism where the stereogenic center from the last enchained monomer unit influences the stereochemical outcome of subsequent monomer addition. Notably, this propagation scheme becomes competitive with an enantiomorphic-site control pathway in the case of some (salen)CoX catalysts, resulting in a loss of syndiospecificity. Based on the results presented above, we believe that an enantiomorphic-site control mechanism is competitive for (salen)CoX catalysts with a sterically bulky diimine backbone or cumyl ortho and para phenolate substituents. Also, in the case of catalyst rac -(salen-8) $\mathrm{CoOBzF}_{5}$, where the steric bulk of the salen ligand is minimal, all stereochemical direction is lost, showing that moderate ligand steric bulk is necessary for chainend control. Overall, the optimized ligand structure for maximum catalyst activity and syndiospecificity is achieved with minimal steric bulk on the salen diimine backbone and tert-butyl moieties present in the ortho and para positions of the phenolate.

In an effort to investigate the relationship between PCHC tacticity and the applied $\mathrm{CO}_{2}$ pressure, we proceeded to explore a series of (salen) CoX catalysts for the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization at low $\mathrm{CO}_{2}$ pressures ( 6.8 atm ) (Table 4). In all cases, catalyst activity decreased notably and reaction times were increased to 48 h or longer in order to achieve appreciable conversion. In addition, the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerizations at low $\mathrm{CO}_{2}$ pressures generally resulted in a loss of syndiospecificity and decreased carbonate incorporation in the resultant PCHC. Catalyst $(R, R)$ -(salen-1)CoBr showed no syndiospecificity yielding atactic PCHC with only $90 \%$ carbonate incorporation (entry 1). Using our

Table 3 Effect of phenolate substituents: (salen) $\mathrm{CoOBzF}_{5}\left(\left[\mathrm{OBzF}_{5}\right]=\right.$ pentafluorobenzoate $)$ catalyzed $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization ${ }^{a}$

${ }^{a}$ Copolymerizations run in neat cyclohexene oxide $(\mathrm{CHO})$ at $22^{\circ} \mathrm{C}$ with $[\mathrm{CHO}]:[\mathrm{Co}]=500: 1$ at 6.8 atm of $\mathrm{CO}_{2}$. In all cases, cyclohexene carbonate byproduct is not observed as determined by ${ }^{1} \mathrm{H}$ NMR spectroscopy $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right)$. ${ }^{b}$ Based on isolated poly(cyclohexene carbonate) yield. ${ }^{c}$ Turnover frequency $=\mathrm{mol} \mathrm{CHO}(\mathrm{mol} \mathrm{Co})^{-1} \mathrm{~h}^{-1}$. ${ }^{d}$ Determined by ${ }^{1} \mathrm{H}$ NMR spectroscopy $\left(\mathrm{CDCl}_{3}, 300 \mathrm{MHz}\right)$. ${ }^{e}$ Determined by gel permeation chromatography calibrated with polystyrene standards in tetrahydrofuran at $40^{\circ} \mathrm{C}$. ${ }^{f}$ Determined by ${ }^{13} \mathrm{C} \mathrm{NMR}$ spectroscopy ( $\mathrm{CDCl}{ }_{3}, 125 \mathrm{MHz}$ ).
most sterically bulky complex $(R, R)$-(salen-11) CoBr, however, surprisingly produced isoenriched PCHC with $65 \% m$-centered tetrads and $99 \%$ carbonate incorporation (entry 2 ). Interestingly, the sterically bulky catalyst $(R, R)$-(salen-2) CoBr incorporated very little $\mathrm{CO}_{2}$, producing predominantly poly(cyclohexene oxide) (entry 3). One of our best catalysts at high pressure (rac-(salen6) $\mathrm{CoOBzF}_{5}$ ) showed a decrease in syndiospecificity with $\mathrm{CO}_{2}$ at 6.8 atm generating PCHC with only $60 \% r$-centered tetrads and $88 \%$ carbonate linkages (entry 4), whereas changing its axial ligand to Br completely eliminated its syndiospecificity (entry 5). To further correlate $\mathrm{CO}_{2}$ pressure to catalyst activity and syndiospecificity, we continued to investigate the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization using rac-(salen-6) $\mathrm{CoOBzF}_{5}$ at a series of different $\mathrm{CO}_{2}$ pressures. Results from these experiments are presented graphically in Fig. 7. It is notable that 54.4 atm is highest pressure we are able to obtain at $22^{\circ} \mathrm{C}$ using our standard copolymerization setup and was therefore the highest pressure applied. Decreasing the $\mathrm{CO}_{2}$ pressure from 54.4 atm to 47.6 atm caused a dramatic loss in catalyst activity, consistent with the results we observe with (salen)CoX catalysts for $\mathrm{PO} / \mathrm{CO}_{2}$ copolymerization. ${ }^{5}$ Further reductions in $\mathrm{CO}_{2}$ pressure resulted in a slow but steady decrease in catalyst activity. The syndiospecificity of catalyst rac-(salen6) $\mathrm{CoOBzF}_{5}$ is optimized at 54.4 atm of $\mathrm{CO}_{2}$ and parallels the catalyst activity at all pressures employed.

Fig. 7 Effect of $\mathrm{CO}_{2}$ pressure on catalyst activity and syndiospecificity of $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization with rac-(salen-6) $\mathrm{CoOBzF}_{5}$.

Alternating copolymerization of cyclohexene oxide and carbon dioxide with (salen)CoX catalysts and [PPN]Cl cocatalysts. Previous investigations have shown the addition of organic ionic cocatalysts to porphyrin- or salen-supported catalysts for epoxide/ $\mathrm{CO}_{2}$ copolymerization often results in increased reaction rates. ${ }^{3,4,6-8,17 b}$ In our earlier work, addition of $[\mathrm{PPN}] \mathrm{Cl}$ to $(R, R)$-(salen-1) $\mathrm{CoOBzF}_{5}$ for $\mathrm{PO} / \mathrm{CO}_{2}$ copolymerization led to a dramatic increase in reaction rate as compared with the use of $(R, R)$-(salen $-\mathbf{1}) \mathrm{CoOBzF}_{5}$ alone. ${ }^{6}$ In addition, $(R, R)$-(salen1) $\mathrm{CoOBzF}_{5} /[\mathrm{PPN}] \mathrm{Cl}$ was most active for $\mathrm{PO} / \mathrm{CO}_{2}$ copolymerization at low $\mathrm{CO}_{2}$ pressures, which has allowed the development of optimized systems functioning under only 6.8 atm of $\mathrm{CO}_{2}$. Based on these findings, we decided to test the effect of $[\mathrm{PPN}] \mathrm{Cl}$ in the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization using a series of (salen) $\mathrm{CoX}(\mathrm{X}=$ $\mathrm{Br}, \mathrm{OBzF}_{5}$ ) under various reaction conditions (Table 5).

We initially applied $[\mathrm{PPN}] \mathrm{Cl}$ cocatalysts to the (salen) CoX catalyzed $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization at high $\mathrm{CO}_{2}$ pressures in an effort to maximize the catalyst syndiospecificity. Interestingly, catalyst system $(R, R)$-(salen -1$) \mathrm{CoBr} /[\mathrm{PPN}] \mathrm{Cl}$ showed a loss in syndiospecificity from use of $(R, R)$-(salen-1) CoBr alone. Additionally, only a small increase in activity was observed upon the addition of the $[\mathrm{PPN}] \mathrm{Cl}$ cocatalyst. By varying the catalyst axial ligand in $(R, R)$-(salen-1) $\mathrm{CoX} /[\mathrm{PPN}] \mathrm{Cl}$ from Br to $\mathrm{OBzF}_{5}$ we observe little change in activity and syndiospecificity (entries 1 and 2). Surprisingly, catalyst rac -(salen-6) $\mathrm{CoOBzF}_{5}$, one of the fastest catalysts without an additive, was less active for $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization upon the inclusion of [PPN]Cl (entry 3). Similar to the $(R, R)$-(salen) $\mathrm{CoX} /[\mathrm{PPN}] \mathrm{Cl}\left(\mathrm{X}=\mathrm{Br}, \mathrm{OBzF}_{5}\right)$ catalyst systems, little syndiospecificity was realized in this case.

The loss of syndiospecificity upon the addition of [PPN]Cl to the (salen) CoX catalyzed $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization indicates that a chain-end control mechanism exerts less control on the stereospecificity of the polymerization. We therefore explored (salen) $\mathrm{CoOBzF}_{5}$ catalysts with sterically bulky salen ligands in an effort to invoke a site-control mechanism for isotactic PCHC. Application of $(R, R)$-(salen-2) $\mathrm{CoOBzF}_{5} /[\mathrm{PPN}] \mathrm{Cl}$, with a more sterically bulky diimine backbone, had comparable activity to $(R, R)$ -(salen-1) $\mathrm{CoOBzF}_{5} /[\mathrm{PPN}] \mathrm{Cl}$ however the resultant PCHC was atactic (entry 4). Additionally, employing a more sterically bulky phenolate moiety $\left((R, R)-(\right.$ salen -11$\left.) \mathrm{CoOBzF}_{5} /[\mathrm{PPN}] \mathrm{Cl}\right)$ also generated atactic PCHC with slightly lower activity (entry 5). In general, addition of $[\mathrm{PPN}] \mathrm{Cl}$ cocatalysts to (salen)CoX catalyzed $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization at high $\mathrm{CO}_{2}$ pressures results in a loss in stereospecificity with little or no increase in activity.

Table 5 Effect of $[\mathrm{PPN}] \mathrm{Cl}$ cocatalyst: (salen) $\mathrm{CoX} /[\mathrm{PPN}] \mathrm{Cl}$ catalyzed copolymerization of CHO and $\mathrm{CO}_{2}\left(\mathrm{X}=\mathrm{Br}, \mathrm{OBzF}_{5}\left(\mathrm{OBzF}_{5}=\right.\right.$ pentafluorobenzoate) ${ }^{a}$

${ }^{a}$ Copolymerizations run in neat cyclohexene oxide $(\mathrm{CHO})$ at $22{ }^{\circ} \mathrm{C}$ with $[\mathrm{CHO}]:[\mathrm{Co}]:[[\mathrm{PPN}] \mathrm{Cl}]=1000: 1: 1$. In all cases, cyclohexene carbonate byproduct is not observed and product poly(cyclohexene carbonate)s have $\geq 97 \%$ carbonate linkages as determined by ${ }^{1} \mathrm{H}$ NMR spectroscopy ( $\mathrm{CDCl}_{3}$, $300 \mathrm{MHz}) .{ }^{b}$ Based on isolated PCHC yield. ${ }^{c}$ Turnover frequency $=\mathrm{mol} \mathrm{CHO}(\mathrm{mol} \mathrm{Co})^{-1} \mathrm{~h}^{-1} .{ }^{d}$ Determined by gel permeation chromatography calibrated with polystyrene standards in tetrahydrofuran at $40^{\circ} \mathrm{C}$. ${ }^{e}$ Determined by ${ }^{13} \mathrm{C}$ NMR spectroscopy ( $\mathrm{CDCl}_{3}, 125 \mathrm{MHz}$ ). ${ }^{f} 70{ }^{\circ} \mathrm{C}$.

At low $\mathrm{CO}_{2}$ pressures ( 6.8 atm ), catalyst activities increase dramatically upon the addition of [PPN]Cl to the copolymerization, although product PCHCs become virtually atactic. Catalyst systems $(R, R)$-(salen-1) $\mathrm{CoX} /[\mathrm{PPN}] \mathrm{Cl}\left(\mathrm{X}=\mathrm{Br}, \mathrm{OBzF}_{5}\right)$ are highly active with TOFs of 110 and $160 \mathrm{~h}^{-1}$, respectively, producing atactic PCHC (entries 6 and 7). rac-(salen-6) $\mathrm{CoOBzF}_{5} /[\mathrm{PPN}] \mathrm{Cl}$ was less active for $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization with a TOF of $90 \mathrm{~h}^{-1}$ (entry 8 ), while use of the more sterically bulky $(R, R)$-(salen2) $\mathrm{CoOBzF}_{5} /[\mathrm{PPN}] \mathrm{Cl}$ or $(R, R)$-(salen-11) $\mathrm{CoOBzF}_{5} /[\mathrm{PPN}] \mathrm{Cl}$ resulted in even lower TOFs of 65 and $31 \mathrm{~h}^{-1}$ (entries 9 and 10). Overall, when using the cocatalyst $[\mathrm{PPN}] \mathrm{Cl},(R, R)$-(salen-1) $\mathrm{CoOBzF}_{5}$ is the most active catalyst for $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization at low $\mathrm{CO}_{2}$ pressures.

Although use of elevated temperatures for $(R, R)$-(salen1) $\mathrm{CoOBzF}_{5} /[\mathrm{PPN}] \mathrm{Cl}$ catalyzed $\mathrm{PO} / \mathrm{CO}_{2}$ copolymerization predominantly forms propylene carbonate, we did not observe the analogous cyclohexene carbonate upon heating the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization. Furthermore, at the optimized temperature of $70{ }^{\circ} \mathrm{C}$, catalyst system $(R, R)$-(salen-1) $\mathrm{CoOBzF}_{5} /[\mathrm{PPN}] \mathrm{Cl}$ generates PCHC with a TOF of $440 \mathrm{~h}^{-1}$ (entry 11). Overall, this is the fastest catalyst activity we observe with the (salen)CoX/[PPN]Cl systems, although it still is inferior to zinc- and chromium-based alternatives. ${ }^{1}$

Stereochemical characterization and analysis of poly(cyclohexene
carbonate). In previous accounts, stereoregular PCHC has been classified according to the relative stereochemistry of the carbons on the cyclohexane units at which the main chain enters (Fig. 8(a))..$^{14,19}$ In all reported cases to date, the main chain bonds entering and leaving the enchained cyclohexane units of PCHC are oriented trans to each other. Furthermore, although stereoregular PCHC is conventionally a ditactic polymer, ${ }^{24}$ assigning the relative stereochemistry for the carbons at which the main chain leaves provides no additional stereochemical information and has therefore been generally omitted (Fig. 8(b)). In keeping with the previously established conventions in this field, it is important to note that $[\mathrm{m}]$ and $[r]$ assignments used herein represent the relative stereochemistry of the carbons of the cyclohexane units at which the main chain enters (Fig. 8(a)), not the relative stereochemistry of the two carbons on either side

syndiotactic $=$ rrr

Fig. 8 Classification of poly(cyclohexene carbonate) according to the relative stereochemistry of the carbon at which the main chain enters the cyclohexane unit (a), the carbon at which the main chain enters and leaves the cyclohexane unit (b) and adjacent carbons (c).
of the carbonate unit (Fig. 8(c)). Therefore a racemic diad ([r]) represents two entire monomer units that have been incorporated in the opposite stereochemical orientation.

In earlier reports, we and Nozaki assigned the carbonyl region of the ${ }^{13} \mathrm{C}$ NMR spectrum for isotactic $\mathrm{PCHC},{ }^{13,14}$ which was further corroborated using statistical methods. ${ }^{14}$ Additionally, Nozaki has assigned the resonances corresponding to $[\mathrm{mmm}]$ and $[\mathrm{rrr}]$ tetrad sequences by synthesizing model polycyclohexene carbonate oligomers. ${ }^{19}$ In each case, all $[\mathrm{mmm}],[\mathrm{mmr}]$ and $[\mathrm{rmr}]$ tetrads were correlated to one central resonance at 153.7 ppm and the remaining $r$-centered tetrads resided in the $153.3-153.1 \mathrm{ppm}$ range. Isotactic PCHC was therefore characterized by a strong resonance at 153.7 ppm with a smaller series of resonances from 153.3153.1 ppm due to stereoerrors. Statistically (enantiomorphic-site control), the most prominent stereoerrors in isotactic PCHC are [ mrr$]$ and $[\mathrm{mmr}]$ tetrads, with much smaller contributions from the remaining $[r r r],[r m r]$ and $[\mathrm{mrm}]$ tetrads. In contrast, the PCHC
that we obtain with catalyst rac -(salen-6) $\mathrm{CoOBzF}_{5}$ revealed a ${ }^{13} \mathrm{C}$ NMR spectrum with four distinct resonances at 152.94 , $153.06,153.12$ and 153.70 ppm integrating to $9,56,24$ and $11 \%$, respectively (Fig. 9(a)). ${ }^{22}$ The peak at 152.94 ppm is unique to this polymer and was unobserved in isotactic PCHC. ${ }^{14,19}$ Based on the previous assignments, we correlated the most intense resonance at 153.06 ppm to the $[\mathrm{rrr}]$ tetrad, with a relative integration of $56 \%$. Using Bernoullian (chain-end control) statistical methods, such that the calculated probability of a racemo diad $\left(P_{\mathrm{r}}\right)$ was determined by the maximized weighted fit between calculated and

Fig. 9 Carbonyl region of the ${ }^{13} \mathrm{C}$ NMR spectra ( $125 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) of poly(cyclohexene carbonate)s generated using $\mathrm{CHO} / \mathrm{CO}_{2}$ ( 54.4 atm ) with catalyst rac-(salen-6) $\mathrm{CoOBzF}_{5}$ (a), $\mathrm{CHO} / \mathrm{CO}_{2}$ (54.4 atm) with catalyst $(R, R)$-(salen -1$) \mathrm{CoOBzF}_{5}(\mathrm{~b}), \mathrm{CHO} / \mathrm{CO}_{2}(54.4 \mathrm{~atm})$ with catalyst rac-(salen-8) $\mathrm{CoOBzF}_{5}$ (c) and $\mathrm{CHO} / \mathrm{CO}_{2}$ ( 6.8 atm ) with catalyst ( $R, R$ )-(salen-11) $\mathrm{CoBr}(\mathrm{d})$.
observed (obs) tetrad concentrations we calculate $56 \%[r r r]$ tetrads, $24 \%[\mathrm{rrm}]$ tetrads and $12 \%[\mathrm{rmr}]$ tetrads, with the remaining tetrads: $[\mathrm{mmr}]=5 \%,[\mathrm{mrm}]=2 \%$ and $[\mathrm{mmm}]=1 \%$ (Table 6 ). ${ }^{25}$ The previous reports assigning all $m$-centered tetrads to a central resonance at 153.7 ppm do not agree with these statistical calculations. We therefore propose that the $[\mathrm{rmr}]$ tetrad corresponds to the most upfield resonance at 152.94 ppm in our spectrum, an unobservable stereoerror in isotactic PCHC samples, due to its low probability, leading to a previously incorrect assignment. It is also important to note that the $[\mathrm{rmr}]$ tetrad was not investigated in previous syntheses of model oligomers, ${ }^{19}$ precluding its direct assignment through chemical means. Finally, we attribute the resonance at 153.11 ppm to the $[\mathrm{rrm}]$ sequence, leaving the remaining [ mmr ] and [mmm] tetrads collectively at 153.70 ppm and the negligible $[\mathrm{mrm}]$ tetrad absent. It is notable that the $[\mathrm{rrm}]$ resonance in the ${ }^{13} \mathrm{C}$ NMR spectrum of isotactic PCHC (Fig. 9(d)) is shifted 0.1 ppm upfield from that of syndiotactic PCHC (Fig. 9(a) and (b)), which we attribute to the minor influence of the long-range polymer tacticity on this shift.
To further support the $\mathrm{PCHC}{ }^{13} \mathrm{C}$ NMR assignments that we propose, we applied Bernoullian statistical methods and compared the observed concentration of each tetrad with its corresponding calculated amount. Table 6 compares observed tetrad concentrations to their calculated statistical occurrences for a series of syndiotactic PCHCs. In most cases, the observed and calculated concentrations are in close agreement, and are within the expected error of the deconvolution methods used. Notably, the PCHCs with the highest observed \% $r$-centered tetrads overall have relative tetrad concentrations that best agree with the corresponding calculated values.
The ${ }^{13} \mathrm{C}$ NMR spectrum of less syndiotactic PCHC , as generated from catalyst $(R, R)$-(salen-1) $\mathrm{CoOBzF}_{5}$ shows the $[r r r]$ and $[r r m]$ tetrad resonances approach each other in magnitude with a more significant contribution from the $[\mathrm{mmm}]$ and $[\mathrm{mmr}]$ tetrads (Fig. 9(b)). Using Bernoullian statistical methods, we calculate relative tetrad occurrences of $[\mathrm{mmm}]+[\mathrm{mmr}]=15 \%,[\mathrm{rmr}]=$ $15 \%,[\mathrm{rrr}]=35 \%,[\mathrm{rrm}]=29 \%$ and $[\mathrm{mrm}]=6 \%$ (Table 6). This is indeed consistent with what we observe, where a previously minor resonance at 153.18 ppm is now more prominent, which we assign to the $[\mathrm{mrm}]$ tetrad. In this spectrum we detect fine splitting of various resonances in the $153.2-152.9 \mathrm{ppm}$ region and hypothesize that due to the increase of PCHC stereoerrors we are able to

${ }^{a}$ Calculated (calc.) statistical occurrences for each tetrad were determined through application of Bernoullian (chain-end control) statistical methods where the calculated probability of a racemo diad $\left(P_{\mathrm{r}}\right)$ was determined by the maximized weighted fit between calculated and observed (obs.) tetrad concentrations. All observed values determined by quantitative ${ }^{13} \mathrm{C}$ NMR spectroscopy ( $\mathrm{CDCl}_{3}, 125 \mathrm{MHz}$ ) with deconvolution of ${ }^{13} \mathrm{C}$ NMR resonances. In all cases, the $[\mathrm{mrm}]$ tetrad concentrations (calc values between 2-7\%) were too small for analysis by the deconvolution methods used and were therefore omitted.
observe signals at greater than tetrad resolution. Furthermore, the ${ }^{13} \mathrm{C}$ NMR spectrum of the same PCHC sample using a lower resolution spectrometer showed only the five resonances at 152.95, $153.06,153.12,153.17$ and 153.70 ppm .
The ${ }^{13} \mathrm{C}$ NMR spectrum of PCHC , as generated from catalyst rac-(salen-8) $\mathrm{CoOBzF}_{5}$, reveals that the $[\mathrm{mmm}]+[\mathrm{mmr}]$ tetrads integrate equally to those of the remaining tetrads, indicative of the formation of atactic polymer (Fig. 9(c)). Finally, isoenriched PCHC , as generated from catalyst $(R, R)$-(salen-11) CoBr while carrying out the $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization at low $\mathrm{CO}_{2}$ pressures ( 6.8 atm ), has a ${ }^{13} \mathrm{C}$ NMR spectrum similar to that of previously reported isotactic PCHC. ${ }^{13,14}$ In this case we observe a large resonance correlating to the combined $[\mathrm{mmm}]+[\mathrm{mmr}]$ tetrads at 153.70 ppm and additional resonances representing the $[\mathrm{rrm}]$ and $[\mathrm{mrm}]$ stereoerrors with no detectable $[\mathrm{rrr}]$ or $[\mathrm{rmr}]$ tetrads (Fig. 9(d)).

The methylene regions in the $\mathrm{PCHC}{ }^{13} \mathrm{C}$ NMR spectra also vary with PCHC stereochemistry (Fig. 10). In the case of syndiotactic PCHC, two series of two adjacent resonances are observed which we assign to the $[r r]$ and $[m r]$ triads corresponding to the nonequivalent methylene carbons in the PCHC backbone (Fig. 10(a)). In each case, the $[\mathrm{mr}]$ and $[\mathrm{rm}]$ triad resonances cannot be distinguished. Furthermore, we suspect that one of these two triads has the same ${ }^{13} \mathrm{C}$ NMR shift as the $[r r]$ triad. The ${ }^{13} \mathrm{C}$ NMR spectrum of less syndiotactic PCHC shows $[r r]$ triads of decreased intensity

Fig. 10 Methylene region of the ${ }^{13} \mathrm{C}$ NMR spectra ( $125 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) of poly(cyclohexene carbonate)s generated using $\mathrm{CHO} / \mathrm{CO}_{2}$ ( 54.4 atm ) with catalyst rac-(salen-6) $\mathrm{CoOBzF}_{5}$ (a), $\mathrm{CHO} / \mathrm{CO}_{2}$ (54.4 atm) with catalyst $(R, R)$-(salen-1) $\mathrm{CoOBzF}_{5}(\mathrm{~b}), \mathrm{CHO} / \mathrm{CO}_{2}(54.4 \mathrm{~atm})$ with catalyst rac-(salen-8) $\mathrm{CoOBzF}_{5}$ (c) and $\mathrm{CHO} / \mathrm{CO}_{2}(6.8 \mathrm{~atm})$ with catalyst ( $R, R$ )-(salen-11) $\mathrm{CoBr}(\mathrm{d})$.
relative to the $[\mathrm{mr}]$ triad resonances and additional downfield resonances are detected which we assign to the $[\mathrm{mm}]$ triads (Fig. 10(b)). Alternatively, the ${ }^{13} \mathrm{C}$ NMR spectrum of atactic PCHC reveals more intense $[\mathrm{mm}]$ triad resonances compared to the syndiotactic PCHC samples, with the $[\mathrm{mr}]$ and $[r r]$ triad resonances also present (Fig. 10(c)). In this case, we observe some tetrad resolution where the $[r r]$ triad resonances are split into their $[r r m]$ and $[r r r]$ components and the $[\mathrm{mr}]$ triad resonances are broadened. Finally, the ${ }^{13} \mathrm{C}$ NMR spectrum of isoenriched PCHC shows that the downfield $[\mathrm{mm}]$ triad resonances in the methylene region have the greatest intensities relative to the $[\mathrm{mr}]$ and $[r r]$ triad signals (Fig. 10(d)).

## Conclusions

We have explored a series of (salen)CoX catalysts for the alternating copolymerization of CHO and $\mathrm{CO}_{2}$. These catalysts provide a viable route to syndiotactic PCHC , a previously unreported PCHC microstructure. The structural properties of the salen ligand in these catalysts dictate the syndiotacticity of the resultant PCHC, a correlation which we attribute to a competition of chain-end and enantiomorphic-site control mechanisms. Additionally, catalyst syndiospecificity is pressure dependent, with the best selectivity realized employing high $\mathrm{CO}_{2}$ pressures. PCHC with as high as $81 \% r$-centered tetrads was obtained using this class of catalyst. Inclusion of [PPN]Cl cocatalysts to the (salen)CoX catalyzed $\mathrm{CHO} / \mathrm{CO}_{2}$ copolymerization results in an increase in catalyst activity in most cases with an overall loss in syndiospecificity. Under optimized conditions, these systems achieve a TOF of $440 \mathrm{~h}^{-1}$ for the generation of PCHC.

## Experimental

## Materials and physical measurements

All air- or water-sensitive reactions were carried out under dry nitrogen using an MBraun Labmaster drybox or standard Schlenkline techniques. Methylene chloride and diethyl ether were dried and degassed by passing through a column of activated alumina and by sparging with dry nitrogen. $(S, S)$ - and $(R, R)-N, N^{\prime}-$ bis(3,5-di-tert-butylsalicylidene)-1,2-diaminocyclohexane cobalt $((S, S)$-(salen-1)Co and ( $R, R$ )-(salen-1)Co) were purchased from Aldrich and recrystallized from methylene chloride and methanol. Bis(triphenylphosphine)iminium chloride ( $[\mathrm{PPN}] \mathrm{Cl}$ ) was purchased from Strem and recrystallized from dry methylene chloride and diethyl ether under nitrogen before use. CHO was dried over calcium hydride and vacuum transferred before use. $\mathrm{CO}_{2}$ ( $99.998 \%$ purity) was purchased from Airgas and passed over a column of $4 \AA$ molecular sieves. All other reagents were purchased from commercial sources and used as received. Varian Mercury ( 300 MHz ) and Inova ( 500 MHz ) spectrometers were used to record ${ }^{1} \mathrm{H}$ NMR spectra, which were referenced $v s$. residual nondeuterated solvent shifts. An Inova ( 500 MHz ) spectrometer was used to record ${ }^{13} \mathrm{C}$ NMR spectra (at 125 MHz ), which were referenced vs. residual deuterated solvent shifts. $\mathrm{C}_{6} \mathrm{~F}_{6}(-162.90 \mathrm{ppm})$ was used as an internal reference for all ${ }^{19} \mathrm{~F}$ NMR spectra. GPC analyses were carried out using a Waters instrument (M515 pump, U6 K injector) equipped with Waters UV486 and Waters 2410 detectors, and four $5-\mu \mathrm{m}$ PL Gel columns (Polymer Laboratories; 100, 500, $1000 \AA$ and Mixed C porosities) in series. The GPC columns were eluted
with THF at $40{ }^{\circ} \mathrm{C}$ at $1 \mathrm{~mL} \min ^{-1}$ and were calibrated using 23 monodisperse polystyrene standards. IR spectra were measured on a Mattson Research Series FTIR. High resolution mass spectra were obtained from the Mass Spectrometry Laboratory, School of Chemical Sciences, University of Illinois. All (salen) CoX ( $\mathrm{X}=\mathrm{Br}$ or $\mathrm{OBzF}_{5}$ ) complexes reveal axial ligand (X) loss in the (EI) mass spectra attributable to the poor stability of this complex under the applied conditions. In the case of all (salen) $\mathrm{CoOBzF}_{5}$ complexes, carbons on the phenyl group of pentafluorobenzoate were not assigned in the ${ }^{13} \mathrm{C}$ NMR spectra due to complex carbon fluorine splitting patterns.

## Ligand preparation

Schiff-base condensation of salicylaldehydes with 1,2-diamines to generate salen-type ligands is readily achieved by refluxing 2 eq of the parent aldehyde and 1 equiv of the parent diamine in absolute ethyl alcohol. ${ }^{26}$ In most cases, 3 h reaction time is sufficient for obtaining high product yields. Following the removal of solvent in vacuo, the crude yellow solid is recrystalized from ethyl alcohol yielding the product salen ligand in most cases. Alternatively, the tartrate salt of the parent diamine can be employed in the synthesis, where the diamine tartrate is stirred with $\mathrm{K}_{2} \mathrm{CO}_{3}$ in water until dissolution prior to reaction with the aldehyde. ${ }^{27}$ The analytical data and synthetic modifications for new salen ligands are listed below:
(Salen-4) $\mathbf{H}_{2}$. To a solution of 3,5-di-tert-butyl-2-hydroxybenzaldehyde ( $3.0 \mathrm{~g}, 13 \mathrm{mmol}$ ) in ethyl alcohol ( 60 mL ) was added 2-methyl-1,2-propanediamine ( $0.67 \mathrm{~mL}, 6.4 \mathrm{mmol}$ ) and the mixture was refluxed for 3 h . The reaction was cooled to $22^{\circ} \mathrm{C}$, and the solvent was removed in vacuo. The crude yellow solid was recrystalized from ethyl alcohol at $-20^{\circ} \mathrm{C}$ affording yellow needles ( $3.1 \mathrm{~g}, 93 \%$ ). ${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}, 500 \mathrm{MHz}$ ): $\delta 1.28(\mathrm{~s}, 9 \mathrm{H})$, $1.29(\mathrm{~s}, 9 \mathrm{H}), 1.43(\mathrm{~s}, 24 \mathrm{H}), 3.71(\mathrm{~s}, 2 \mathrm{H}), 7.07\left(\mathrm{~d},{ }^{4} \mathrm{~J}=4.5 \mathrm{~Hz}, 1 \mathrm{H}\right)$, $7.09\left(\mathrm{~d},{ }^{4} J=4.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.35\left(\mathrm{~d},{ }^{4} J=4.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 7.36(\mathrm{~d}$, $\left.{ }^{4} J=4.5 \mathrm{~Hz}, 1 \mathrm{H}\right), 8.35(\mathrm{~s}, 1 \mathrm{H}), 8.39(\mathrm{~s}, 1 \mathrm{H}) 13.67(\mathrm{~s}, 1 \mathrm{H}), 14.21(\mathrm{~s}$, $1 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR ( $\mathrm{CDCl}_{3}, 125 \mathrm{MHz}$ ): $\delta 25.73,29.60,29.63,31.63$, $31.66,34.26,35.17,35.19,60.14,70.71,117.99,118.08,126.22$, $126.35,126.90,127.18,136.78,136.80,139.98,140.12,158.32$, 158.52, 162.88, 167.78. HRMS (ESI) $m / z$ calc. $\left(\mathrm{C}_{34} \mathrm{H}_{52} \mathrm{~N}_{2} \mathrm{O}_{2}+\right.$ $\mathrm{H}^{+}$) 521.4107, found 521.4110.
rac-(Salen-7)H2. 3,5-Bis( $\alpha, \alpha^{\prime}$-dimethylbenzyl)-2-hydroxybenzaldehyde ${ }^{28}(0.59 \mathrm{~g}, 1.6 \mathrm{mmol})$, 1,2-diaminopropane ( $68 \mu \mathrm{~L}$, $0.80 \mathrm{mmol})$ and ethyl alcohol $(10 \mathrm{~mL})$ were mixed and the reaction was heated at reflux for 12 h . The reaction was cooled to $22^{\circ} \mathrm{C}$, and the solvent was removed in vacuo. Following recrystallization from ethyl alcohol, the product was collected as yellow needles $(0.41 \mathrm{~g}, 68 \%) .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 500 \mathrm{MHz}\right): \delta 1.25\left(\mathrm{~d},{ }^{3} J=4 \mathrm{~Hz}\right.$, $3 \mathrm{H}), 1.595(\mathrm{~s}, 3 \mathrm{H}), 1.599(\mathrm{~s}, 3 \mathrm{H}), 1.61(\mathrm{~s}, 3 \mathrm{H}), 1.62(\mathrm{~s}, 3 \mathrm{H}), 1.698$ $(\mathrm{s}, 3 \mathrm{H}), 1.702(\mathrm{~s}, 3 \mathrm{H}), 3.58-3.75(\mathrm{~m}, 3 \mathrm{H}), 7.13-7.32(\mathrm{~m}, 24 \mathrm{H})$, $8.23(\mathrm{~s}, 1 \mathrm{H}), 8.27(\mathrm{~s}, 1 \mathrm{H}), 13.34(\mathrm{br} \mathrm{s}, 2 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}, 125\right.$ $\mathrm{MHz}): \delta 20.56,29.29,29.73,29.92,31.05,31.06,31.08,42.27$, 42.31, 42.54, 65.08, 65.80, 118.01, 125.17, 125.70, 125.73, 125.76, 126.84, 127.91, 127.98, 127.15, 129.34, 136.00, 136.17, 139.62, 139.69, 150.71, 150.84, 150.85, 157.69, 157.88, 165.17, 166.97. ## Preparation of (salen)Co complexes

Complexes $(R, R)$-(salen-1)Co and ( $S, S$ )-(salen-1)Co are commercially available. All other (salen)Co complexes were prepared according to the general procedure for the synthesis of (salen4)Co. Complexes $(R, R)$-(salen-2)Co, ${ }^{30}$ (salen-3)Co, ${ }^{31}$ and (salen5) $\mathrm{Co}^{32}$ prepared by this method are in agreement with literature characterization. The analytical data and synthetic modifications for new (salen)Co complexes are listed below:
(Salen-4)Co. (Salen-4) $\mathrm{H}_{2}(2.3 \mathrm{~g}, 4.4 \mathrm{mmol})$ and cobalt acetate tetrahydrate $(1.3 \mathrm{~g}, 5.2 \mathrm{mmol})$ were added to a Schlenk flask charged with a Teflon stir bar under $\mathrm{N}_{2}$. A 1:1 mixture of toluene and methanol ( 100 mL ); (degassed for 20 min by sparging with dry $\mathrm{N}_{2}$ ) was added and stirred at $22{ }^{\circ} \mathrm{C}$ for 2 h . The resultant red precipitate was filtered in air and washed with distilled water $(50 \mathrm{~mL})$ and methanol ( 50 mL ) and collected as a crude solid ( 2.3 g , $90 \%$ yield). IR (KBr, $\mathrm{cm}^{-1}$ ): 786, 842, 871, 1178, 1255, 1318, 1363, 1390, 1464, 1528, 1595, 2870, 2909, 2959. HRMS (ESI) $m / z$ calc. $\left(\mathrm{C}_{34} \mathrm{H}_{50} \mathrm{CoN}_{2} \mathrm{O}_{2}\right)$ 577.3204, found 577.3226.
rac-(Salen-6)Co. Employing the same reaction conditions as for (salen-4)Co, rac-(salen-6) $)^{10}(2.8 \mathrm{~g}, 5.5 \mathrm{mmol})$ and cobalt acetate tetrahydrate ( $1.7 \mathrm{~g}, 6.8 \mathrm{mmol}$ ) in a $1: 1$ mixture of degassed toluene and methanol $(150 \mathrm{~mL})$ were stirred for 6 h to afford a crude red solid ( $2.9 \mathrm{~g}, 95 \%$ ). IR ( $\mathrm{KBr}, \mathrm{cm}^{-1}$ ): 787, 837, 874, 1179, 1204, 1255, 1320, 1361, 1385, 1466, 1528, 1596, 2871, 2909, 2956. HRMS (ESI) $m / z$ calc. $\left(\mathrm{C}_{33} \mathrm{H}_{48} \mathrm{CoN}_{2} \mathrm{O}_{2}\right) 563.3048$, found 563.3046.
rac-(Salen-7)Co. Employing the same reaction conditions as for (salen-4)Co, rac-(salen-7) $(0.30 \mathrm{~g}, 0.40 \mathrm{mmol})$ and cobalt acetate tetrahydrate $(0.12 \mathrm{~g}, 0.48 \mathrm{mmol})$ in a $1: 1$ mixture of degassed toluene and methanol $(10 \mathrm{~mL})$ were stirred for 3 h to afford a crude red solid ( $0.25 \mathrm{~g}, 77 \%$ ). IR ( $\mathrm{KBr}, \mathrm{cm}^{-1}$ ) 765, 777, 787, 818, 873, 957, 1031, 1106, 1166, 1226, 1323, 1370, 1427, 1441, 1497, 1526, 1583, 1607, 2904, 2926, 2966, 3060. HRMS (ESI) $\mathrm{m} / \mathrm{z}$ calc. $\left(\mathrm{C}_{53} \mathrm{H}_{56} \mathrm{CoN}_{2} \mathrm{O}_{2}\right)$ 811.3674, found 811.3698.
rac-(Salen-8)Co. Employing the same reaction conditions as for (salen-4)Co, the crude yellow oil rac-(salen-8) ( $2.1 \mathrm{~g}, 6.8 \mathrm{mmol}$ ) was dissolved in a $1: 1$ mixture of degassed toluene and methanol $(40 \mathrm{~mL})$ and cobalt acetate tetrahydrate ( $2.0 \mathrm{~g}, 8.0 \mathrm{mmol}$ ) was added under $\mathrm{N}_{2}$ and stirred for 1 h to afford a crude red-brown solid ( $1.9 \mathrm{~g}, 76 \%$ ). IR ( $\mathrm{KBr}, \mathrm{cm}^{-1}$ ) 739, 888, 947, 1106, 1120, 1234, 1318, 1376, 1419, 1451, 1545, 1604, 2920, 2966, 3020, 3439. HRMS (ESI) $m / z$ calc. $\left(\mathrm{C}_{19} \mathrm{H}_{20} \mathrm{CoN}_{2} \mathrm{O}_{2}\right) 367.0857$, found 367.0843 .
rac-(Salen-9)Co. Employing the same reaction conditions as for (salen-4)Co, the crude yellow oil rac-(salen-9) ( $2.2 \mathrm{~g}, 5.6 \mathrm{mmol}$ ) was dissolved in a $1: 1$ mixture of degassed toluene and methanol $(40 \mathrm{~mL})$ and cobalt acetate tetrahydrate ( $1.6 \mathrm{~g}, 6.4 \mathrm{mmol}$ ) was added under $\mathrm{N}_{2}$ and stirred for 3 h to afford a crude red solid $(1.4 \mathrm{~g}, 55 \%)$. IR ( $\mathrm{KBr}, \mathrm{cm}^{-1}$ ) 753, 869, 886, 952, 1057, 1086, 1147, 1200, 1235, 1266, 1316, 1386, 1408, 1466, 1535, 1597, 2873, 2921, 2953. HRMS (ESI) $m / z$ calc. $\left(\mathrm{C}_{25} \mathrm{H}_{32} \mathrm{CoN}_{2} \mathrm{O}_{2}\right) 451.1796$, found 451.1776.
rac-(Salen-10)Co. Employing the same reaction conditions as for (salen-4)Co, rac-(salen-10) $(0.22 \mathrm{~g}, 0.40 \mathrm{mmol})$ and cobalt acetate tetrahydrate $(0.12 \mathrm{~g}, 0.48 \mathrm{mmol})$ in a $1: 1$ mixture of degassed toluene and methanol $(7 \mathrm{~mL})$ were used to afford a crude red solid $(0.10 \mathrm{~g}, 41 \%)$. IR ( $\mathrm{KBr}, \mathrm{cm}^{-1}$ ) 734, 783, 865, 1179, 1310, 1385, 1402, 1525, 1592, 2873, 2922, 2957. HRMS (ESI) $m / z$ calc. $\left(\mathrm{C}_{25} \mathrm{H}_{30} \mathrm{Br}_{2} \mathrm{CoN}_{2} \mathrm{O}_{2}\right)$ 607.0006, found 607.0010.
( $\boldsymbol{R}, \boldsymbol{R}$ )-(Salen-11)Co. Employing the same reaction conditions as for (salen-4)Co, $(R, R)$-(salen-7) $(0.69 \mathrm{~g}, 0.87 \mathrm{mmol})$ and cobalt acetate tetrahydrate $(0.26 \mathrm{~g}, 1.0 \mathrm{mmol})$ in a $1: 1$ mixture of degassed toluene and methanol ( 30 mL ) were used to afford a crude red solid $(0.59 \mathrm{~g}, 80 \%)$. IR ( $\mathrm{KBr}, \mathrm{cm}^{-1}$ ): 766, 809, 1034, 1105, 1246, 1325, 1340, 1362, 1459, 1528, 1605, 2872, 2937, 2968, 3026, 3061, 3453. HRMS (ESI) $m / z$ calc. $\left(\mathrm{C}_{56} \mathrm{H}_{60} \mathrm{CoN}_{2} \mathrm{O}_{2}\right)$ 851.3987, found 851.3972.

## Preparation of (salen) $\mathrm{CoX}\left(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{OAc}, \mathrm{OBzF}_{5}\right)$ complexes

The synthesis of (salen-1)CoX $\left(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{OAc}, \mathrm{OBzF}_{5}\right)$ have been described previously. ${ }^{6,20,21}$ A modified procedure as reported by Jacobsen and coworkers ${ }^{21}$ for the synthesis of $(R, R)$-(salen1) CoCl was applied to the synthesis of all (salen) CoBr complexes with the substitution of NaBr for NaCl .
( $\boldsymbol{R}, \boldsymbol{R}$ )-(Salen-2)CoBr. $\quad(R, R)$-(salen-2)Co $(0.25 \mathrm{~g}, 0.36 \mathrm{mmol})$ and $p$-toluenesulfonic acid monohydrate ( $68 \mathrm{mg}, 0.36 \mathrm{mmol}$ ) were added to a 50 mL round bottomed flask charged with a Teflon stir bar. Methylene chloride ( 10 mL ) was added to the reaction mixture and stirred for 2 h open to air at $22^{\circ} \mathrm{C}$. The solvent was removed by rotary evaporation at $22^{\circ} \mathrm{C}$, and the crude solid was washed with pentane $(100 \mathrm{~mL})$ and filtered. The crude material was dissolved in methylene chloride ( 25 mL ) and added to a 125 mL separatory funnel. The organic layer was rinsed with saturated aqueous $\mathrm{NaBr}(3 \times 25 \mathrm{~mL})$. The organic layer was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and evaporated under reduced pressure. The solid was washed with pentane $(100 \mathrm{~mL})$ and filtered to afford $(R, R)$-(salen2) $\mathrm{CoBr}(0.12 \mathrm{~g}, 43 \%)$. ${ }^{1} \mathrm{H}$ NMR (DMSO- $\left.d_{6}, 500 \mathrm{MHz}\right): \delta 1.22(\mathrm{~s}$, $18 \mathrm{H}), 1.76(\mathrm{~s}, 18 \mathrm{H}), 5.62(\mathrm{~s}, 2 \mathrm{H}), 6.97(\mathrm{~s}, 2 \mathrm{H}), 7.23(\mathrm{~s}, 2 \mathrm{H}), 7.41-$ $7.48(\mathrm{~m}, 12 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR (DMSO- $d_{6}, 125 \mathrm{MHz}$ ): $\delta 30.37,31.35$, $33.31,35.73,76.61,117.64,128.48,129.18,129.90,134.93,136.07$, 142.02, 162.31, 166.50. Following the salt metathesis a crude black solid was obtained ( $0.16 \mathrm{~g}, 29 \%$ ). ${ }^{1} \mathrm{H}$ NMR (DMSO$\left.d_{6}, 500 \mathrm{MHz}\right): \delta 1.50(\mathrm{~m}, 2 \mathrm{H}), 1.57(\mathrm{~s}, 6 \mathrm{H}), 1.58(\mathrm{~s}, 6 \mathrm{H}), 1.76$ $(\mathrm{s}, 6 \mathrm{H}), 1.84(\mathrm{~m}, 2 \mathrm{H}), 1.93(\mathrm{~m}, 2 \mathrm{H}), 2.29(\mathrm{~s}, 6 \mathrm{H}), 2.92(\mathrm{~m}, 2 \mathrm{H})$, $3.39(\mathrm{~m}, 2 \mathrm{H}), 6.98\left(\mathrm{~d},{ }^{4} J=3.0 \mathrm{~Hz}, 2 \mathrm{H}\right), 7.06\left(\mathrm{tt},{ }^{3} J=9.0 \mathrm{~Hz}\right.$, $\left.{ }^{4} J=2.0 \mathrm{~Hz}, 2 \mathrm{H}\right), 7.12-7.28(\mathrm{~m}, 18 \mathrm{H}), 7.45\left(\mathrm{~d},{ }^{4} J=2.5 \mathrm{~Hz}\right.$, 2H), 7.75 (s, 2H). ${ }^{13} \mathrm{C}$ NMR (DMSO- $d_{6}, 125 \mathrm{MHz}$ ): $\delta 24.19$, 27.92, 27.98, 29.56, 30.31, 30.42, 30.51, 30.54, 32.55, 41.43, 41.57, 41.90, 43.36, 69.07, 118.92, 125.09, 125.35, 125.39, 125.52, 126.17, $126.20,126.37,127.66,127.74,127.88,127.94,130.80,133.02$, 135.11, 135.14, 141.02, 150.72, 151.20,161.90, 164.70. HRMS (EI) $m / z$ calc. $\left(\mathrm{C}_{56} \mathrm{H}_{60} \mathrm{BrCoN}_{2} \mathrm{O}_{2}-\mathrm{Br}\right) 851.3987$, found 851.3984.
$(\boldsymbol{R}, \boldsymbol{R})$-(Salen-11) $\mathbf{C o O B z F}_{5}$. Employing the same reaction conditions as for $(R, R)$-(salen-2) $\mathrm{CoOBzF}_{5},(R, R)$-(salen-11) Co $(0.25 \mathrm{~g}, 0.29 \mathrm{mmol})$ and pentafluorobenzoic acid ( 62 mg , $0.29 \mathrm{mmol})$ were used to afford the crude green product $(0.21 \mathrm{~g}$, $68 \%) .{ }^{1} \mathrm{H}$ NMR (DMSO- $\left.d_{6}, 500 \mathrm{MHz}\right): \delta 1.48(\mathrm{~m}, 2 \mathrm{H}), 1.57(\mathrm{~s}$, $6 \mathrm{H}), 1.58(\mathrm{~s}, 6 \mathrm{H}), 1.75(\mathrm{~s}, 6 \mathrm{H}), 1.85(\mathrm{~m}, 2 \mathrm{H}), 1.94(\mathrm{~m}, 2 \mathrm{H}), 2.29(\mathrm{~s}$, $6 \mathrm{H}), 2.92(\mathrm{~m}, 2 \mathrm{H}), 3.38(\mathrm{~m}, 2 \mathrm{H}), 6.98(\mathrm{~s}, 2 \mathrm{H}), 7.07\left(\mathrm{t},{ }^{3} \mathrm{~J}=7.0 \mathrm{~Hz}\right.$, 2H), $7.12-7.28(\mathrm{~m}, 18 \mathrm{H}), 7.45\left(\mathrm{~d},{ }^{4} \mathrm{~J}=2.5 \mathrm{~Hz}, 2 \mathrm{H}\right), 7.76(\mathrm{~s}, 2 \mathrm{H}) .{ }^{13} \mathrm{C}$ NMR (DMSO- $d_{6}, 125 \mathrm{MHz}$ ): $\delta 24.09,28.80,29.45,30.19,30.30$, $32.47,41.33,43.25,68.96,118.82,124.97,125.23,126.06,127.63$, $127.76,130.71,132.90,135.03,140.90,150.61,151.10,161.80$, 164.61. ${ }^{19} \mathrm{~F}$ NMR (DMSO- $d_{6}, 470 \mathrm{MHz}$ ): $\delta-163.66,-162.78$, -144.92. HRMS (EI) $m / z$ calc. $\left(\mathrm{C}_{63} \mathrm{H}_{60} \mathrm{CoF}_{5} \mathrm{~N}_{2} \mathrm{O}_{4}-\mathrm{C}_{7} \mathrm{~F}_{5} \mathrm{O}_{2}\right)$ 851.3987, found 851.3984.

## Representative copolymerization procedure

A 100 mL Parr autoclave was heated to $120^{\circ} \mathrm{C}$ under vacuum for 4 h , then cooled under vacuum to $22{ }^{\circ} \mathrm{C}$ and moved to a drybox. Complex rac-(salen-6)CoOBzF $5_{5}(15.6 \mathrm{mg}, 0.0201 \mathrm{mmol})$ and CHO ( $1.00 \mathrm{~mL}, 9.88 \mathrm{mmol}$ ) were placed in a glass sleeve with a Teflon stir bar inside the Parr autoclave. The autoclave was pressurized to 54.4 atm of $\mathrm{CO}_{2}$ and was left to stir at $22^{\circ} \mathrm{C}$ for 3 h . The reactor was vented at $22^{\circ} \mathrm{C}$. A small aliquot of the resultant polymerization mixture was removed from the reactor for ${ }^{1} \mathrm{H}$ NMR and GPC analysis. The remaining polymerization mixture was then dissolved in methylene chloride ( 5 mL ), quenched with $5 \% \mathrm{HCl}$ solution in methanol $(0.2 \mathrm{~mL})$, and precipitated from methanol ( 30 mL ). The polymer was collected and dried in vacuo to constant weight, and the polymer yield was determined $(0.799 \mathrm{~g}$, $56.9 \%$ ).

## Crystallographic data for structures rac-(salen-1) CoI and ( $\boldsymbol{R}, \boldsymbol{R}$ )-(salen-1) $\mathbf{C o C l}$

rac-(salen-1) $\mathbf{C o I} \cdot \mathbf{C H}_{2} \mathbf{C l}_{\mathbf{2}} \cdot \mathbf{0 . 5} \mathrm{C}_{6} \mathbf{H}_{14} \cdot \quad T=173(2) \mathrm{K}, \mathrm{C}_{40} \mathrm{H}_{61}-$ $\mathrm{Cl}_{2} \mathrm{CoIN}_{2} \mathrm{O}_{2}, M_{\mathrm{r}}=858.64$, triclinic, space group $P \overline{1}$ (no. 2); $a=10.969(4), b=12.522(5), c=16.694(7) \AA, a=97.299(9)$, $\beta=105.834(9), \gamma=106.802(9)^{\circ}, V=2058.3(14) \AA^{3}, Z=2$, $\mu=1.331 \mathrm{~mm}^{-1} ; 10442$ reflections collected and 6822 independent reflections ( $R_{\text {int }}=0.0493$ ). Final $R$ indices $[I>2 \sigma(I)] R 1=0.0562$, $w R 2=0.1100 ; R$ indices (all data) $R 1=0.0996, w R 2=0.1232$.
$(\boldsymbol{R}, \boldsymbol{R})$-(salen-1)CoCl$\cdot \mathbf{2 C} \mathbf{C}_{6} \mathbf{H}_{6} . \quad T=173(2) \quad \mathrm{K}, \mathrm{C}_{96} \mathrm{H}_{128} \mathrm{Cl}_{2} \mathrm{Co}_{2}-$ $\mathrm{N}_{4} \mathrm{O}_{4}, M_{\mathrm{r}}=1590.78$, monoclinic, space group $P 2_{1}$ (no. 4); $a=$
14.5088(11), $b=10.1068(6), c=29.765(2) \AA, \beta=105.834(9)^{\circ}$, $V=4355.9(5) \AA^{3}, Z=2, \mu=0.494 \mathrm{~mm}^{-1} ; 23614$ reflections collected and 8926 independent reflections ( $R_{\text {int }}=0.0679$ ). Final $R$ indices $[I>2 \sigma(I)] R 1=0.0589$, $w R 2=0.1325 ; R$ indices (all data) $R 1=0.0808, w R 2=0.1408$.

Crystallographic details for (salen-1) $\mathrm{CoX}(\mathrm{X}=\mathrm{Cl}, \mathrm{I})$ are summamized in the ESI. $\dagger$

22 Quantitative ${ }^{13} \mathrm{C}$ NMR spectra of PCHC were deconvoluted prior to integration in order to subtract out the $[\mathrm{rmr}]$ resonance from the remaining resonances in the $153.2-152.9 \mathrm{ppm}$ regime. This provided for an approximation of the $\% r$-centered tetrads in the PCHC.
