# Metal-assisted Cycloadditions. Part 2.t Reactions of Dicarbonyl( $\eta^{5}$ -  and Acetylenes 

By Raymond Baker,* Christopher M. Exon, and V. Bhaskar Rao, Department of Chemistry, The University, Southampton SO9 5NH<br>Ralph W. Turner, Imperial Chemical Industries Limited (Pharmaceuticals Division), Mereside Alderley Park, Macclesfield, Cheshire SK10 4TG

#### Abstract

Dicarbonyl( $\eta^{\mathbf{5}}$-cyclopentadienyl) ( $\eta^{1}$-3-methoxyallyl) iron has been treated with ethyl 3,3-dicyanoacrylate, diethyl 1 -cyanoethylenedicarboxylate, ethyl 2,3-dicyanoacrylate, diethyl methylenemalonate, and trimethyl ethylenetricarboxylate to yield the corresponding cyclopentyl- Fp derivatives [ $\mathrm{Fp}=\mathrm{Fe}(\mathrm{CO})_{2}$ (cyclopentadienyl)] as a mixture of diastereoisomers and these have been separated by column chromatography. The Fp-moiety of these cyclopentyl-Fp adducts has been replaced with an alkoxycarbonyl group by treatment with ceric ammonium nitrate. Substituted cyclopentene derivatives have been isolated from the reaction of these Fp -adducts with either hydrogen chloride or trityl tetrafluoroborate.

Reaction of ( $\eta^{1}$-allyl)dicarbonyl( $\eta^{5}$-cyclopentadienyl)iron (1) with tetracyanoethylene ${ }^{\mathbf{1}}$ and a variety of other electrophilic, unsaturated moieties ${ }^{2-7}$ has been shown to yield cyclopentanoid derivatives via a cycloaddition process. In the preceding paper we reported ${ }^{8}$ the reactions of complex (1) with a number of cyano- and alkoxycarbonyl-substituted alkenes and the results of demetallation of the cycloaddition products by a number of methods. From these reactions it was clear that a particular requirement for the cycloaddition reaction was that the olefin must be electron deficient. It was considered that the use of an electron rich ( $\eta^{1}$-allyl)-Fp complex $\left[\mathrm{Fp}=\mathrm{Fe}(\mathrm{CO})_{2}\right.$ (cyclopentadienyl) $]$ might extend the scope of these processes. Dicarbonyl $\eta^{5}$-cyclopentadienyl)( $\eta^{1}-3$-methoxyallyl)iron (2) has been prepared ${ }^{2}$ and its reactions with a variety of electron-deficient olefins and acetylenes were studied.

## RESULTS AND DISCUSSION

Reaction of ( $\eta^{1}-3$-methoxyallyl)-Fp (2) with ethyl 3-3-dicyanoacrylate (3a) in dichloromethane at room temperature yielded a mixture of the two isomeric products (4a) and (5a) (Scheme 1), which were easily separated by column chromatography on Florisil, and were isolated in a $3: 2$ ratio, respectively. $\ddagger$ Formation of four diastereoisomers was a possibility from this reaction, but earlier studies by Rosenblum et al. ${ }^{3}$ have indicated that the geometrical relationship of Fp and the C-3 substituent in complex (2) is retained in the cyclic adducts, thus the cis-geometrical relationship associated with the methoxy- and Fp-groups of the allyl complex (2) is

[^0]retained in the products. The structure (4a) (Scheme 1 ) was assigned to the major product as $2-\mathrm{H}$ resonated as a doublet of doublets in the ${ }^{1} \mathrm{H}$ n.m.r. spectrum (Table 3), which indicated a $\beta, \beta, \alpha$-configuration for $1-, 2-$, and $3-\mathrm{H}$, respectively. However, $2-\mathrm{H}$ resonated as a triplet in the

spectrum of the minor product, indicating that $1-, 2-$, and $3-\mathrm{H}$ are $\beta, \beta, \beta-$, respectively, as in complex ( 5 a ).

Mixtures of the cyclic products (4b), and (5b) (4c) + $(4 \mathrm{~d})$, and $(5 \mathrm{c})+(5 \mathrm{~d})$ were also obtained with diethyl l-cyanoethylene-1,2-dicarboxylate (3b), ethyl 2,3-dicyanoacrylate (3c), and its isomer (3d), respectively. The ratio in which adducts were isolated depended upon the olefin employed (Table 1). Lower yields of the cyclopentanoid derivatives were obtained, even after longer reaction times, with diethyl methylenemalonate (3e) and trimethyl ethylenetricarboxylate (3f), probably due to the decreased reactivity of these olefins.

It is likely that the allyl complex would approach the olefin such that the methoxy- and $\mathrm{R}^{3}$-substituents are in the more sterically favoured trans-configuration in the dipolar intermediate (7). Two processes could be postulated which would initially give this configuration [Scheme 2, (a) and (b)]. In the case of diethyl 1-cyanoethylene-1,2-dicarboxylate (3b), the considerable steric bulk of the ester groups would be expected to

favour the latter of these two processes [Scheme 2, (b)] resulting in the formation of complex (5b) in higher yield. By replacing one of the ester groups with a cyano-group, the steric hindrance may be reduced to such an extent that either the former process [Scheme 2, (a)] predominates, as with ethyl 3,3-dicyanoacrylate (3a), or that the olefin can approach the allyl complex equally from any direction, giving a $50: 50$ mixture, as with ethyl 2,3-dicyanoacrylate (3c) $+(3 \mathrm{~d})$.

It was discovered that column chromatography on neutral alumina eliminated methanol from the adducts (4a) and (5a), yielding (6b) (Scheme 1). In general, complex (4a) was isolated in low yield ( $<15 \%$ ) from the column, whereas complex (5a) always gave the product
of elimination (6b), providing further evidence that these adducts have the stereochemistry shown since, even in a cyclopentyl derivative, a trans-E2 elimination reaction is probably more favoured. However, no elimination of methanol was apparent from the adducts (4b)-(4d) and (5b)-(5d) (Scheme 1).

Reaction of ( $\eta^{1}-3$-methoxyallyl)-Fp (2) with dimethyl acetylenedicarboxylate (DMAD) has been found to be relatively slow when compared with the reactions with olefinic esters. Thus, reaction of complex (2) with DMAD ( 10 equiv.) in dimethylformamide (DMF) for 45 h at room temperature yielded $66 \%$ of the cyclic product (6a). This yield was, however, improved to $77 \%$ when the reaction was conducted with 4 equiv. of DMAD for a

period of 48 h , followed by addition of another 2 equiv. and stirring for a further 24 h . Unlike in other cases, no improvement of yield of complex (6a) was obtained ( $51 \%$ ) when the solvent was changed to dichloromethane. Isolation of the single cyclic product (6a) in a shorter time from the reaction of complex (2) with DMAD indicated its enhanced reactivity when compared with its simple allyl analogue (1), which yielded a mixture of linear and cyclic adducts. The absence of linear products from the former reaction might be due to the presence of the 3 -methoxy-group in complex (2) which could disfavour abstraction of hydrogen from C-3 in the intermediate zwitterion (7).

Demetallation Reactions.-For the cycloaddition reactions to be of synthetic use in organic chemistry, methods for the removal or replacement of the Fp moiety in complexes (4), (5), and (6) by a suitable organic function are required. Demetallation reactions of these products have been studied under a variety of conditions.
(i) Oxidative carboxylation. The replacement of the Fp-group with a carboxylic ester function has been readily achieved by the oxidation of alcoholic solutions of alkyl-Fp complexes with cupric chloride, ${ }^{9,10}$ ceric salts, ${ }^{11,12}$ oxygen, or bromine. ${ }^{10}$ Treatment of alcoholic solutions of the Fp-complexes (4a)-(4d), (5a)-(5d), and
(6a) with ammonium ceric nitrate, in the presence of carbon monoxide, resulted in the corresponding carboxylated derivatives (8), (9), and (10) (Scheme 3, Table 4).

(4)

(5)

Scheme 2
It was concluded that the oxidative carboxylation of complexes (4) and (5) proceeded with retention of configuration, ${ }^{9}$ since only one methoxy-group resonance appeared in the ${ }^{1} \mathrm{H}$ n.m.r. spectra of the crude products.

${ }^{a}$ All the products indicated a strong peak at $\nu c a .1740 \mathrm{~cm}^{-1}$; all these oily liquids were eluted from the column with ether-light petroleum (1:1). ${ }^{b}$ Isolated yield. $c$ Isolated as a mixture of isomers. d Ref. 1.
resonances in the ${ }^{1} \mathrm{H}$ n.m.r. spectra of the chromatographed products. This isomerisation of compounds (9a)-(9d) provides further evidence of an all cisarrangement of substituents as shown in structure (9), which would be expected to rearrange on the column to the structure with the more stable configuration. The low isolated yield of compound ( 10 ) ( $25 \%$ ) is considered to be due to decomposition during chromatography, as the ${ }^{1} \mathrm{H}$ n.m.r. spectrum of the crude product indicated its quantitative formation.
(ii) Acid cleavage. In contrast with the oxidative cleavage of the Fp-moiety, very few acid cleavages have
been investigated. ${ }^{13.14}$ Treatment of a dichloromethane solution of the cyclopentyl-Fp complexes (4b) or (5b) with hydrogen chloride for 1 h resulted in exclusive formation of compound (12) in yields of $75-81 \%$. The i.r. spectrum of the crude reaction mixture indicated that the reaction proceeded via the Fp-( $\eta^{1}$-olefin) cation (ll) (Scheme 4). Similar observations were made earlier ${ }^{15}$ in the treatment of a 2 -methoxyethyl-Fp complex with hydrogen chloride, which resulted in the formation of a Fp-( $\eta$-ethylene) cation. Treatment of an ethanolic solution of compound (12) with sodium ethoxide gave compound (13), in which the olefinic proton resonated

Schfme 4 Reageuts: i, $\mathrm{HCl}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$ : ii, NaOF t. iii, $\mathrm{Ph}_{3} \mathrm{CBF}_{4}$; iv, NaI, Ac Me
as a triplet ( $\delta 7.15, J 2 \mathrm{~Hz}$ ). The adduct (4a) also gave the eliminated product (14) in $56 \%$ yield on reaction with HCl (Scheme 4).
(iii) $\beta$-Hydride abstraction. Conversion of alkyl-Fp complexes into Fp -( $\eta$-olefin) cations followed by treatment with sodium iodide with liberation of an alkene has been developed previously ${ }^{\mathbf{1 2}, 16,17}$ as a method for replacement of the Fp-group. Treatment of the Fpcomplex (4b) with trityl tetrafluoroborate followed by reaction of the intermediate Fp -( $\eta^{1}$-olefin)-tetrafluoroborate salt (15) (Scheme 4) with sodium iodide in acetone gave compound (12) as the exclusive product in $62 \%$ yield.

The presence of the 2 -methoxy-group in the cyclo-pentyl-Fp complexes (4) and (5) facilitates the easy cleavage of the Fp -moiety with hydrogen chloride and trityl tetrafluoroborate, resulting in formation of the cyclopentene derivatives (12) and (14). This is in contrast with the simple cyclopentyl-Fp adducts derived from ( $\eta^{1}$-allyl)-Fp (1) which, with HCl , yielded a mixture of cyclic and linear products ${ }^{8}$ by opening of the cyclopentane ring. This might be due to the greater ease of formation of the Fp -( $\eta^{2}$-olefin) salt (11) by the elimination of the 2 -methoxy-group, preceded by protonation.

## EXPERIMENTAL

All operations were performed as described previously. ${ }^{8}$ Dicarbonyl ( $r^{5}$-cyclopentadienyl)( $\eta^{1}$-3-methoxyallyl)iron (2) was prepared following the procedure of Rosenblum et al. ${ }^{2}$ and used in the reactions. $\mathrm{Fp}=$ dicarbonyl $\left(\eta^{5}\right.$-cyclopentadienyl)iron, $\mathrm{Cp}=$ cyclopentadienyl, ether refers to diethyl ether, and $v$ is given in $\mathrm{cm}^{-1}$.

Reactions of Complex (2) with the Electron-deficient Olefins (3a)-(3f).-General procedure. To a solution of the allyl complex (2) (ca. 2 mmol ) in either dimethylformamide (DMF) or $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5-15 \mathrm{ml})$ (Table 1) was added the olefin (3) ( $1-10$ equiv.) dissolved in the same solvent ( $1-5 \mathrm{ml}$ ). The mixture was stirred at room temperature (Table 1). After removal of the solvent under reduced pressure (DMF at 0.1 Torr and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at 14 Torr) the crude product was chromatographed with a $20 \mathrm{~mm} \times 30 \mathrm{~cm}$ column. The residue was, in general, applied to the column as a solution in benzene ( $2-5 \mathrm{ml}$ ), the solvent being removed on elution with light petroleum followed by elution with ether-light petroleum (Table 2).

All the products * showed satisfactory spectral (Table 3) and analytical data (Table 2).

I:limination of Methanol from Complexes (4a) and (5a).Reaction of the 3 -methoxyallyl complex (2) ( $645 \mathrm{mg}, 2.6$

[^1]mmol ) with ethyl 3,3 -dicyanoacrylate (3a) ( $412 \mathrm{mg}, 2.7$ mmol ) was carried out in dichloromethane ( 20 ml ) employing the standard reaction procedure. Column chromatography of the crude product, obtained after removal of the solvent under reduced pressure, on neutral alumina (Act-III) afforded the cyclic adduct (4a) [ $153 \mathrm{mg}, 13 \%$, ether-light petroleum ( $1: 1$ ) as eluant] and dicarbonyl $\left(\eta^{5}\right.$-cyclopentadienyl)( $\eta^{1}$-4,4-dicyano-3-ethoxycarbonylcyclopent-2-enyl)iron ( 6 b ), eluted by ether (Scheme 1, $287 \mathrm{mg}, 32 \%$ ); $\nu_{\text {max. }}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) 2242 \mathrm{w}(\mathrm{C} \equiv \mathrm{N}) .2010,1970 \mathrm{~s}(\mathrm{C} \equiv \mathrm{O}), 1700 \mathrm{~s}$ $(\mathrm{C}=\mathrm{O})$, and $1595 \mathrm{~m}(\mathrm{C}=\mathrm{C})$; $\delta 1.37\left(3 \mathrm{H}, \mathrm{t}, \mathrm{CO}_{2} \mathrm{CH}_{2} \mathrm{Me}\right)$, $2.64 \mathrm{br}(1 \mathrm{H}, \mathrm{dd}, 5-\mathrm{H}), 3.12-3.4(1 \mathrm{H}, \mathrm{m}, 5-\mathrm{H}), 3.56(1 \mathrm{H}, \mathrm{m}$, $1-\mathrm{H}), 4.34 \mathrm{br}\left(2 \mathrm{H}, \mathrm{q}, \mathrm{OCH}_{2}\right), 4.9(5 \mathrm{H}, \mathrm{s}, \mathrm{Cp})$, and 7.39 br ( $1 \mathrm{H}, \mathrm{d}, J 2.5 \mathrm{~Hz}, 2-\mathrm{H}$ ).

Reaction of Complex (2) with Dimethyl Acetylenedicarboxylate ( $D M A D$ ) ——DMAD ( $0.8 \mathrm{ml}, c a .6 \mathrm{mmol}$ ) was added in one portion to a solution of the allyl complex (2) ( 367 mg , 1.5 mmol ) in DMF ( 10 ml ). After the mixture had been stirred for 48 h , an additional 2 equiv. of DMAD $(0.4 \mathrm{ml}$, $c a .3 \mathrm{mmol}$ ) was added, and the reaction was continued for 24 h . The solvent was removed under reduced pressure and the residue was chromatographed on neutral alumina (ActIII). Dicarbonyl( $\eta^{5}$-cyclopentadienyl)( $\eta^{1-2-m e t h o x y-3,4-~}$ dimethoxycarbonylcyclopent-3-enyl)ivon (6a) ( $446 \mathrm{mg}, 77 \%$ ) was eluted with ether-light petroleum ( $1: 1$ ), and recrystallised from a mixture of hexane-ether to obtain a yellow solid, m.p. $94-96{ }^{\circ} \mathrm{C}$ (Found: C, 52.4; H, 4.7. $\mathrm{C}_{17} \mathrm{H}_{18}{ }^{-}$ $\mathrm{FeO}_{7}$ requires $\left.\mathrm{C}, 52.33 ; \mathrm{H}, 4.65 \%\right)$; $\nu_{\text {max. }}\left(\mathrm{CHCl}_{3}\right) 2000$, $1955 \mathrm{~s}(\mathrm{C} \equiv \mathrm{O}), 1715 \mathrm{~s}\left(\mathrm{CO}_{2} \mathrm{Me}\right)$, and $1632 \mathrm{~m}(\mathrm{C}=\mathrm{C}) ; \delta 2.58$ $3.10\left(3 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right.$ and $\left.\mathrm{l}-\mathrm{H}\right), 3.38(3 \mathrm{H}, \mathrm{s}, \mathrm{OMe}), 3.79$ and 3.81 (each $3 \mathrm{H}, \mathrm{s}, \mathrm{CO}_{2} \mathrm{Me}$ ), 4.26br ( $1 \mathrm{H}, \mathrm{dd}, J c a .4$ and 1.5 $\mathrm{Hz}, 2-\mathrm{H})$, and $4.85(5 \mathrm{H}, \mathrm{s}, \mathrm{Cp})$; $m / e 390\left(M^{+}, 0 \%\right), 237$ (55), 122 (43), 121 (54), 119 (100), 95 (35), 92 (29), and 77 (25).

Oxidative Carboxylation of the Fp -adducts (4), (5), and (6a).-General procedure. To a solution of the Fp-complex [(4), (5), and (6a)] in either anhydrous methanol or ethanol ( 40 ml ), previously purged with carbon monoxide for 2 h , was added ammonium ceric nitrate ( 4 equiv.) in one portion at room temperature. Carbon monoxide was then bubbled through the solution overnight. After removal of the solvent under reduced pressure, water ( 50 ml ) was added to the solid residue and the aqueous solution was extracted with benzene ( $4 \times 25 \mathrm{ml}$ ). The combined organic extracts were dried (anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$ ), after which the solution was filtered, concentrated, and the crude product chromatographed on Florisil with ether-light petroleum as eluant. All the products $\dagger$ showed satisfactory spectral data (Table 4).

Acid Cleavage of the Fp-complexes (4a), (4b), and (5b).General procedure. Hydrogen chloride gas was bubbled through a solution of the Fp -adducts ( $c a .0 .4 \mathrm{mmol}$ ) in dichloromethane (ca. 40 ml ) at $0^{\circ} \mathrm{C}$ for 1 h , and the reaction mixture was then set aside for $c a .20-24 \mathrm{~h}$. After removal of the solvent under reduced pressure, the residue was
$\dagger$ Diethyl 4,4-dicyano-c-2-methoxycyclopentane- $r$-1,t-3dicarboxylate (8a), triethyl l-cyano-c-3-methoxycyclopentane-$r$-1, $t$-2, $c$-4-tricarboxylate (8b), diethyl $1, t$-5-dicyano- $c$-4-methoxy-cyclopentane- $\gamma$-1,3- $c$-dicarboxylate (8c), diethyl 1, $c-5$-dicyano-t-4-methoxycyclopentane- $r$-1,3-t-dicarboxylate (8d), diethyl 4,4-dicyano- $c$-2-methoxycyclopentane- $r$-1,c-3-dicarboxylate (9a), triethyl 1-cyano-c-3-methoxycyclopentane-r-1, c-2, c-4-tricarboxylate ( 9 b ), diethyl 1, $c$-5-dicyano- $c-4$-methoxycyclopentane- $r-1, c-3$ dicarboxylate $(9 \mathrm{c})$, diethyl $1, t-5$-dicyano- $t$-4-methoxycyclo-pentane- $r$-1,t-3-dicarboxylate (9d), and trimethyl 3-methoxy-cyclopent-1-ene-1,2,4-tricarboxylate (10).
dissolved in carbon tetrachloride ( $c a .50 \mathrm{ml}$ ) and exposed to sunlight for 3 h to decompose any FpCl present, during which time a green solid precipitated. This solid was then filtered off, the filtrate concentrated, and the crude product purified by flash chromatography ${ }^{18}$ [silica gel ( 10 g ), 20 mm column]. The yields and spectral data are as given below.
(i) Acid cleavage of complex (4a). When complex (4a) was treated with HCl as described in the above procedure, ethyl 5,5-dicyanocyclopent-2-ene-1-carboxylate (14) was isolated $(56 \%)$ by elution with a mixture of ether-light petroleum (1:1) from the column; $\nu_{\text {max. }}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) 1742 \mathrm{~s}$ $(\mathrm{C}=\mathrm{O})$ ) ; $\delta 1.31$ and 1.36 ( 3 H each $\mathrm{t}, 3: 4$ ratio, $\mathrm{CO}_{2} \mathrm{CH}_{2} \mathrm{Me}$ ), 3.10 and $3.30\left(2 \mathrm{H}, \mathrm{m}, 3: 4\right.$ ratio, $\left.\mathrm{CH}_{2}\right), 3.91(1 \mathrm{H}, \mathrm{s}, \mathrm{CHCO})^{-}$ Et), 4.12-4.33 ( $2 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2}$ ), 6.87 and $6.97 \mathrm{br}(2-\mathrm{H}$, $\mathrm{s}, 3: 4$ ratio, $\mathrm{CH}=\mathrm{C} H)$; $m / e 190\left(M^{+}, 0.1 \%\right)$, 124 (27), 117 (22), 106 (14), 92 (24), 91 (100), and 71 (14).
(ii) Acid cleavage of complexes (4b) and (5b). Similar treatment of complexes (4b) or (5b) with HCl yielded diethyl 1-cyanocyclopent-3-ene-1,2-dicarboxylate (12) (yield $81 \%$ ), eluted by $20 \%$ ether in light petroleum; $v_{\text {max }}$. $1740 \mathrm{~s}\left(\mathrm{C}=\mathrm{O}\right.$, ester) ; $\delta 1.31$ and 1.37 (each $3 \mathrm{H}, \mathrm{t}, \mathrm{CO}_{2^{-}}$ $\mathrm{CH}_{2} \mathrm{Me}$ ), $3.10\left(2 \mathrm{H}, \mathrm{dd}, J 3.5\right.$ and $\left.1.5 \mathrm{~Hz}, \mathrm{CH}_{2}\right), 4.10-4.40$ ( $5 \mathrm{H}, \mathrm{m}, \mathrm{OCH}_{2}$ and CHCO 2 Et$)$, and $5.90 \mathrm{br}(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}=\mathrm{CH})$; $m / e(25 \mathrm{eV}) 237$ ( $M^{+}, 5 \%$ ), 191 (38), 163 (24), 138 (32), 118 (23), 93 (23), 92 (100), 91 (65), and 65 (22). Compound (12b) was obtained from complex (5b) in $75 \%$ yield.

Isomerisation of the Dicarboxylate (12) to the Dicarboxylate (13).-To a solution of compound (12) ( $155 \mathrm{mg}, 0.65 \mathrm{mmol}$ ) in anhydrous ethanol ( 1 ml ) was added sodium ethoxide [prepared from sodium ( $15 \mathrm{mg}, 0.65 \mathrm{mmol}$ )] dissolved in ethanol ( 1 ml ). After being stirred at room temperature for 30 s , the reaction mixture was neutralised with 0.1 N hydrochloric acid and then partitioned between dichloromethane ( 10 ml ) and saturated aqueous sodium chloride $(10 \mathrm{ml})$. The organic layer was separated and the aqueous phase further extracted with dichloromethane ( $4 \times 10 \mathrm{ml}$ ) and the combined extracts were dried (anhydrous $\mathrm{MgSO}_{4}$ ), and concentrated. Flash chromatography, ${ }^{18}$ [silica gel ( 10 g ), 20 mm column] with ether-light petroleum ( $1: 1$ ) as eluant, afforded pure diethyl 1-cyanocyclopent-2-ene-1,2dicarboxylate ( 133 ) as an oily liquid ( $121 \mathrm{mg}, 78 \%$ ); $v_{\text {max }}$ $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) 1720-1745 \mathrm{~s}$ (CO, ester) ; $\delta 1.32$ and 1.35 (each 3 H , each $\left.\mathrm{t}, \mathrm{CO}_{2} \mathrm{CH}_{2} M e\right), 2.44-2.40\left(4 \mathrm{H}, \mathrm{m}, 2 \times \mathrm{CH}_{2}\right)$, 4.29 and 4.31 (each 2 H , each q, $\mathrm{OCH}_{2}$ ), and $7.15 \mathrm{br}(1 \mathrm{H}$, $\left.\mathrm{t}, J 2 \mathrm{~Hz}, \mathrm{H}_{2} \mathrm{CCH}=\mathrm{C}\right)$; $m / e(25 \mathrm{eV}) 237\left(M^{+}, 10 \%\right), 192$ (10), 165 (28), 164 (17), 137 (56), 120 (13), 119 (100), 92 (33), and 91 (24).

The yield of the isomerised product (13) decreased to $38 \%$ when the reaction mixture was stirred for 5 min .
Reaction of the Fp-complex (4b) with Trityl Tetrafluoro-borate.-A solution of trityl tetrafluoroborate ( $90 \mathrm{mg}, 0.27$ $\mathrm{mmol})$ in dichloromethane ( 2 ml ) was added as drops to a solution of complex (4b) ( $119 \mathrm{mg}, 0.27 \mathrm{mmol}$ ) in the same solvent ( 3 ml ) at $45{ }^{\circ} \mathrm{C}$. The reaction was completed by stirring this mixture for 2 h at $45^{\circ} \mathrm{C}$ (monitored by i.r.
spectroscopy); the reaction mixture was then cooled to $0^{\circ} \mathrm{C}$ and the intermediate Fp -( $\eta^{2}$-olefin) salt (15) (Scheme 3) was precipitated by adding ether ( $c a .30 \mathrm{ml}$ ). The solvent was decanted off and the residue washed with ether (ca. 20 ml ) to give the salt (15) ( $112 \mathrm{mg}, 76 \%$ ) (Scheme 3); $\nu_{\text {max. }}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) 2075$ and $2030 \mathrm{~s}(\mathrm{C} \equiv \mathrm{O})$.

To the above salt dissolved in acetone ( 2 ml ) was added sodium iodide ( $63 \mathrm{mg}, 0.42 \mathrm{mmol}$ ) in one portion and the resulting mixture was stirred at room temperature for 1 h . The solvent was removed under reduced pressure and the residue extracted with dichloromethane ( $c a .10 \mathrm{ml}$ ). The extracts were filtered (to remove the excess of sodium iodide) and concentrated. The crude product was then dissolved in carbon tetrachloride ( 20 ml ). The solution was exposed to sunlight for 3 h (to decompose any FpI present), filtered, and the solvent removed under reduced pressure. Flash chromatography [silica gel ( 10 g ) , 20 mm column], with ether-light petroleum ( $1: 4$ ) as eluant, afforded the dicarboxylate (12) [ $39 \mathrm{mg}, 62 \%$ from (4b)].

[^0]:    $\dagger$ Part 1, preceding paper.
    $\ddagger$ The numbering given on the structures in this paper is that used to describe the n.m.r. spectral data and is not necessarily the numbering used in the JUPAC names.

[^1]:    * Dicarbonyl ( $\eta^{5}$-cyclopentadienyl $)\left(\eta^{1-4,4-d i c y a n o-t-3-e t h o x y-~}\right.$ carbonyl-r-2-methoxycyclopentyl)iron (4a), dicarbonyl( $\eta^{1}-\mathrm{t}-4$ -cyano-t-3,c-4-diethoxycarbonyl-r-2-methoxycyclopentyl) $\left(\eta^{5}-c y c l o-\right.$ pentadienyl)iron (4b), dicarbonyl $\left(\eta^{5}\right.$-cyclopentadienyl $)\left(\eta^{1}-\mathrm{t}-3, \mathrm{t}-4\right.$ -dicyano-c-4-ethoxycarbonyl-r-2-methoxycyclopentyl)iron (4c), dicarbonyl $\left(\eta^{5}\right.$-cyclopentadienyl $)\left(\eta^{1}-\mathrm{c}-3, \mathrm{c}-4\right.$-dicyano-t-4-ethoxycarb-onyl-r-2-methoxycyclopentyl)iron (4d), dicarbonyl ( $\eta^{5}$-cyclopentadienyl)( $\eta^{1}-4,4$-diethoxycarbonyl-2-methoxycyclopentyl)iron (4e), dicarbonyl ( $\eta^{5}$-cyclopentadienyl) ( $\eta^{1}-\mathrm{r}-2$-methoxy-c-3,4,4-trimethoxycarbonylcyclopentyl)iron (4f), dicarbonyl( $\eta^{5}$-cyclopentadienyl)( $\eta^{1}-4,4$-dicyano-c-3-ethoxycarbonyl-r-2-methoxycyclopentyl)ivon (5a), dicarbonvl( $\eta^{1}-\mathrm{t}-4-c y a n o-\mathrm{c}-3, \mathrm{c}-4$-diethoxycarbonyl-r-2-methoxycyclopentyl) $\left(\eta^{5}-c y c l o p e n t a d i e n y l\right)$ iron (5b), dicarbonyl( $\eta^{5}$-cyclopentadienyl) ( $n^{1}-\mathrm{c}-3 . \mathrm{t}-4$-dicyano-c-4-ethoxycarbonyl-r-2-methoxycyclopentyl)iron (5c), and dicarbonyl( $\eta^{5}$-cyclopentadienyl)-( $\eta^{1}-\mathrm{t}-3, \mathrm{c}-4-d i-$ cyano-t-4-cthorycarhonyl-r-2-methorycyclopentyl) ivon (5d)
