# Metabolic Products of Phomopsis oblonga. Part 2. ${ }^{1}$ Phomopsolide A and B, Tiglic Esters of Two 6-Substituted 5,6-Dihydro-5-hydroxypyran-2-ones 

John Frederick Grove<br>School of Molecular Sciences, University of Sussex, Brighton, Sussex BN1 9QJ

#### Abstract

Phomopsolide $A$ and $B$, two boring/feeding deterrents for elm bark beetles, produced in vitro by the fungus Phomopsis oblonga, are shown to be (5S,6S)-5,6-dihydro-6-(4-hydroxy-3-oxopent-1Z-enyl)5 -(2-methylbut-2E-enoyloxy)-2H-pyran-2-one and (5S,6S)-5,6-dihydro-6-[(3S,4S)-3,5-dihydroxy-pent-1 $E$-enyl)-5-(2-methylbut-2E-enoyloxy)-2H-pyran-2-one, respectively. Another active compound, (-)-6-(4-hydroxy-3-oxopent-1E-enyl)-2H-pyran-2-one, was also isolated but is considered to be an artefact.

Phomopsis oblonga (Desm.) Trav. produces in vitro a number of boring/feeding deterrents for Scolytid beetles. ${ }^{1.2}$ One of these deterrents, oblongolide, produced in surface culture on malt extract medium by a strain, number 118, of P. oblonga Group 1 was shown ${ }^{1}$ to be the novel norsesquiterpene $\gamma$-lactone (1). This paper describes the isolation and structure determination of a further two active compounds, the $\mathrm{C}_{15}$ dihydropyrones (phomopsolide A (2) and phomopsolide B(3a), produced by the same strain on the same medium but in shake as well as in surface culture. An active $\mathrm{C}_{10}$ pyrone (7) was also isolated but was shown to be an artefact.

Column chromatography of the neutral portion of the ethyl acetate extract of the culture filtrate from a shake fermentation furnished two fractions which showed activity in the bioassay. ${ }^{2}$ Further chromatographic purification of these fractions yielded three active compounds of composition $\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{O}_{4}, \mathrm{C}_{15} \mathrm{H}_{18} \mathrm{O}_{6}$ ( $30-42 \mathrm{mgl}^{-1}$ ) and $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{O}_{6}\left(21-35 \mathrm{mgl}^{-1}\right.$ ), but appreciable variation in the yield of the $\mathrm{C}_{15}$ compounds was obtained in replicate fermentations.
The $\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{O}_{4}$ compound contained two $\mathrm{C}=\mathrm{O}$ groups ( $v_{\text {max. }}$. $1720,1690 \mathrm{~cm}^{-1}$ ) and a secondary hydroxy group [ $v_{\text {max. }} 3450$ $\mathrm{cm}^{-1} ; \delta_{\mathrm{C}} 72.8 ; \delta_{\mathrm{H}} 4.48 \mathrm{q}(J 7.1 \mathrm{~Hz})$ ]. One $\mathrm{C}=\mathrm{O}$ group ( $v_{\text {max. }} 1690$ $\mathrm{cm}^{-1} ; \delta_{\mathrm{c}} 200.5$ ) was conjugated with a trans disubstituted ethylenic double bond [ $\delta_{\mathrm{H}} 7.16 \mathrm{AB}(J 15.4 \mathrm{~Hz}) ; \delta_{\mathrm{C}} 124.4,133.0$ ]. The partial structure (13) suggested by the ${ }^{1} \mathrm{H}$ n.m.r. spectrum (Table 1) was confirmed by the formation of acetaldehyde, isolated as the dinitrophenylhydrazone, on oxidation with periodate. This oxidation also yielded a $\mathrm{C}_{8}$ fission product, the carboxylic acid (10). The u.v. spectrum of the $\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{O}_{4}$ compound [ $\lambda_{\text {max. }} 240,342 \mathrm{~nm}(\log \varepsilon 4.11,4.23)$ ] suggested an $\alpha-$ pyrone ring ( $\mathrm{C}=\mathrm{O}$, $v_{\text {max. }} 1720 \mathrm{~cm}^{-1}$; $\delta_{\mathrm{C}} 160.4$ ) conjugated with the ethylenic linkage. These assignments account for all four oxygen atoms in the molecule which is represented by structure (7). In the ${ }^{1} \mathrm{H}$ n.m.r. spectrum (Table 1) the chemical shifts and coupling constants were in agreement with those recorded for analogous 6 -substituted $\alpha$-pyrones, e.g. sibirinone $(11)^{3}$ and 6 -pent-1-enyl- $\alpha$-pyrone (12). ${ }^{4}$ The ${ }^{13} \mathrm{C}$ resonances (Table 2) likewise generally agreed with those recorded ${ }^{5}$ for analogous structures. Although the optical rotation at 589 nm was close to zero, the pyrone (7) was optically active.

The $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{O}_{6}$ compound, phomopsolide B , contained two $>\mathrm{CHOH}$ groups ( $\delta_{\mathrm{H}} 3.62,3.93$; $\delta_{\mathrm{C}} 76.2,70.6$ ) and formed a diacetate ( $>$ CHOAc: $\delta_{\mathrm{H}} 5.05,5.37$ ). The remaining four oxygen atoms were contained in two ester (or lactone) groups ( $v_{\text {max. }}$ $1728,1710 \mathrm{~cm}^{-1}, \delta_{\mathrm{c}} 162.6,166.7$ ). A feature of the ${ }^{1} \mathrm{H}$ n.m.r. spectrum was (disregarding allylic and homoallylic couplings, see below) the number of one-hydrogen double doublets (see Table 1); taking into account both the chemical shift for each resonance and the coupling constants between olefinic hydrogens, the appropriate decoupling experiments established

(11) $R=M e$
(12) $R=\operatorname{Pr}{ }^{n}$
the presence of the partial structure (14). The remaining seven hydrogens were contained in one CMe and one CHMe group, and their chemical shifts indicated the presence of the partial structure (15). In this structure the $\beta$-olefinic hydrogen is deshielded by $0.5-0.9$ p.p.m. by the cis-alkoxycarbonyl group, ${ }^{6}$ and the chemical shifts indicated a tiglate ( $E$ ) rather than an angelate residue. This was confirmed by the isolation of tiglic acid ( $15 ; \mathrm{R}=\mathrm{H}$ ) on mild alkaline hydrolysis. Partial structures (14) and (15) contain all the carbon atoms of phomopsolide B which is monocyclic. They can be combined in only two ways; the i.r. spectrum is consistent only with the six-membered lactone (dihydropyrone) ring structure (3a). The ${ }^{1} \mathrm{H}$ n.m.r. spectrum (Table 1) showed allylic coupling between the hydrogens at positions $1^{\prime}$ and $3^{\prime}(1.1 \mathrm{~Hz})$ and $2^{\prime}$ and $6(1.1 \mathrm{~Hz})$, and homoallylic coupling ( 0.9 Hz ) between positions 6 and $3^{\prime}$. There was also allylic coupling to $3 "-\mathrm{H}$ in the tiglate residue. The ${ }^{13} \mathrm{C}$ resonances (Table 2) were in close agreement with those recorded for the model compounds ( $15 ; \mathrm{R}=\mathrm{Me}$ ) and (17). As expected, oxidation of the $\alpha$-diol (3a) with periodate gave acetaldehyde and the $\alpha \beta$-unsaturated $\mathrm{C}_{13}$ aldehyde (6), $\lambda_{\text {max. }} 215$ nm .

$\mathrm{R}=p-\mathrm{MeOC}_{6} \mathrm{H}_{4} \mathrm{CO}$
$J_{\mathrm{AA}}$. The latter should be determined for the benzoate derivative selected and in the same solvent that is used for the c.d. measurements.

In this series of compounds, replacing $\mathrm{CDCl}_{3}$ by $\mathrm{CD}_{3} \mathrm{OD}$ as solvent and converting the glycol (3a) into the bis-anisyl derivative (3c) did not alter $J_{3^{\prime} 4^{\prime}}$. The value ( 6.3 Hz ) for $J_{3^{\prime} \mathbf{4}^{\prime}}$ in the derivative (3c) indicated that the hydrogens were trans rather than gauche. ${ }^{12}$ The derivative (3c), $\lambda_{\text {max. }} 260 \mathrm{~nm}$, showed two intense Cotton effects, of similar amplitude but of opposite sign, at $268 \mathrm{~nm}(+\mathrm{ve})$ and $248 \mathrm{~nm}(-\mathrm{ve})$ in the c.d. curve. Only the rotamer (21) (or its mirror image) has trans hydrogens and is capable of showing Cotton effects separated by Davidov splitting. Whilst this rotamer falls into category (19), it is derived from a threo- $x$-glycol, and the positive chirality ${ }^{11}$ indicates a ( $3^{\prime} S, 4^{\prime} S$ ) configuration.

Compared with the phomopsolide B (3a), phomopsolide A contained an additional $\mathrm{C}=\mathrm{O}$ group ( $\delta_{\mathrm{C}} 202.1$ ) but only one $=\mathrm{CHOH}$ group ( $\delta_{\mathrm{C}} 73.2 ; \delta_{\mathrm{H}} 4.36 \mathrm{q}, J 7.1 \mathrm{~Hz}$ ). Although the ${ }^{13} \mathrm{C}$ n.m.r. spectrum (Table 2) was consistent with a close

relationship between the two metabolites, the ${ }^{1} \mathrm{H}$ n.m.r. spectrum revealed a large ( 0.8 p.p.m.) deshielding of the $6-\mathrm{H}$ resonance by the $\mathrm{C}=\mathrm{O}$ group, consistent only with a cis configuration of the $1^{\prime}$-ene ( $J_{1} \cdot 2,11.8 \mathrm{~Hz}$ ) as in structure (2). Despite this structural difference revealed by the spectroscopic data, oxidation of both dihydropyrones with the chromic oxidesulphuric acid reagent ${ }^{14}$ gave the same gummy $\alpha$-diketone (5) characterised, after preparative t.l.c., as the pyrone (9). Although the $x$-glycol (3a) was stable in chloroform in the presence of silica gel, both $3^{\prime}$-oxo compounds (2) and (5) were converted, partially in the case of (3) and quantitatively in the case of (5), into the corresponding pyrones (7) and (9) by the elimination of the elements of tiglic acid. It follows that pyrone (7) is unlikely to be a genuine metabolic product of $P$. oblonga. The formation of the pyrone (7) from phomopsolide A appeared to be preceded by isomerisation of the $1^{\prime}$-ene to the trans-olefin (4), $J_{1}{ }^{\prime} 2^{\prime} 15.5 \mathrm{~Hz}$, which was sometimes isolated. The mechanism of the formation of the racemic pyrone (8), isolated on only one occasion following oxidation of the diol (3a) and chromatographic purification of the product, is uncertain, but may involve an enediol intermediate.

Electron impact mass spectra at 70 ev of the 5-hydroxy-5,6dihydropyrones esterified with tiglic acid showed base peaks at $m / z 83\left(\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}^{+}\right)$, but molecular ions were absent. These were obtained (as $M \mathrm{H}^{+}$peaks) by chemical ionisation using ammonia as reagent gas. The fragmentation pathway for the 6substituted pyrones was straightforward (see Experimental section) combining loss of CO from the pyrone ring with sequential fission of the $\mathrm{C}_{5}$ side chain. After the initial loss of the elements of tiglic acid, the esterified 5-hydroxy-5,6dihydropyrones showed spectra very similar to those given by the corresponding pyrones.

Phomopsolide A and B were also produced in surface culture by strain 118, but in much lower yield ( 14 and $3 \mathrm{mgl}^{-1}$ respectively). Phomopsolide B was produced by Phomopsis sp. strain 124 (ex. sycamore) ${ }^{1}$ in shake ( $8 \mathrm{mgl}^{-1}$ ) but not in surface culture on malt extract medium. With strain 123 (ex. ash) the reverse situation was found and phomopsolide B was produced in high yield ( $63 \mathrm{mg} \mathrm{m}^{-1}$ ) in surface but not at all in shake culture. Neither of these two strains made phomopsolide A. Neither phomopsolide A nor phomopsolide B was produced by the lesscommon Group $2(\operatorname{strain} 119)^{1}$ of $P$. oblonga under any of these culture conditions.

6 -Pentyl-2-pyrones and the corresponding 5 -hydroxy-5,6-dihydro-2-pyrones derived from a pentaketide precursor frequently occur among the secondary metabolic products of fungi, but esterification (of the 5 -hydroxy compounds) with carboxylic acids other than acetic is unusual. Indeed, although esters of tiglic acid are commonly isolated from higher plants they have not hitherto been obtained from fungi. As the free acid was isolated ${ }^{15}$ from crude penicillin, it is presumed to be a metabolic product of Penicillium notatum.

Osmundalactone (18), ${ }^{16}$ the aglycone of the glycoside osmundalin, from the fern Osmunda japonica, has recently ${ }^{17}$ been shown to be a feeding deterrent for larvae of the butterfly Eurema hecabe mandarina. This suggests that the substituted five-carbon side chain and esterification of the 5-hydroxy group in structure (3a) may not be essential for insect feeding deterrent in 5-hydroxy-5,6-dihydro-2-pyrones.

## Experimental

M.p.s were taken on a Kofler hot-stage apparatus and are corrected. Unless otherwise stated, i.r. spectra were determined for mulls in Nujol, and u.v. spectra and c.d. measurements were determined in methanol. N.m.r. spectra were obtained in $\mathrm{CDCl}_{3}$ or $\mathrm{CD}_{3} \mathrm{OD}$ with $\mathrm{SiMe}_{4}$ as internal standard. Molecular weights were taken from the mass spectra. $\mathrm{NH}_{3}$ was used to obtain chemical ionisation mass spectra; the fragmentations recorded (\% base peak in parentheses) are from the electron impact spectra. In analytical t.l.c., Merck silica gel $60 \mathrm{~F}_{254}$ was used with chloroform-methanol (95:5). Merck silica gels 7739 and 7734 were used in preparative t.l.c. ( $0.1-\mathrm{cm}$ layer) and column chromatography respectively. Light petroleum had b.p. $60-$ $80^{\circ} \mathrm{C}$.

Extraction and Isolation of Metabolites from P. oblonga Strain 118.-A. Shake culture. From a typical fermentation on $2 \%$ malt extract medium harvested after 14 days, the culture filtrate ( $3.91, \mathrm{pH} 5.6$ ) was extracted with ethyl acetate. A portion ( 8 mg ) of the extract, a brown oil ( 797 mg ), was retained for bioassay ${ }^{2}$ and the remainder, in benzene ( 10 ml ), was chromatographed on a column ( $50 \times 1.2 \mathrm{~cm}$ ) of silica gel ( 24 g ) made up in benzene. After gummy fractions (total 39 mg ) had been eluted with benzene ( 150 ml ), benzene-methanol ( $200: 1$; $100 \mathrm{ml})$, and benzene-methanol ( $100: 1 ; 100 \mathrm{ml}$ ), further elution with benzene-methanol ( $100: 1 ; 100 \mathrm{ml}$ ) brought off a brown band. A portion ( 201 mg ) of the recovered brown oil ( 351 mg ) was subjected to p.l.c. on four pretreated $40 \times 20 \mathrm{~cm}$ plates developed in chloroform-methanol (20:1) made up from freshly redistilled solvents. The material from two bands, (i) $R_{\mathbf{F}}$ 0.47 and (ii) $R_{\mathrm{F}} 0.35$, visible in u.v. light, was recovered by extraction with redistilled chloroform. (5S,6S)-5,6-Dihydro-6-(4-hydroxy-3-oxopent-1Z-enyl)-5-(2-methylbut-2E-enoyloxy)- $2 \mathrm{H}-$ pyran-2-one (2) (phomopsolide A) was obtained from (i) as a yellow oil ( $92 \mathrm{mg}, 41 \mathrm{mg} / \mathrm{l}), R_{\mathrm{F}} 0.47,[\alpha]_{\mathrm{D}}{ }^{20}+491(c 0.185)$ (Found: C, 60.7; $\mathrm{H}, 6.9 \% ; M \mathrm{H}^{+} 295 . \mathrm{C}_{15} \mathrm{H}_{18} \mathrm{O}_{6}$ requires $\mathrm{C}, 61.2$; $6.2 \%$; M 294); $v_{\text {max }}$.(film) $3450 \mathrm{br}, 1715 \mathrm{br}, 1635 \mathrm{br}, 825,730$ $\mathrm{cm}^{-1} ; \lambda_{\text {max. }} 217 \mathrm{~nm}(\log \varepsilon 4.19)$; $m / z 167.0347$ (12), 150.0347 (50), 149.0256 (33), 122.0393 (51), 100.0520 (37), 95.0155 (50), and $83.0488(100)\left(\mathrm{C}_{8} \mathrm{H}_{7} \mathrm{O}_{4}{ }^{+}, \mathrm{C}_{8} \mathrm{H}_{6} \mathrm{O}_{3}{ }^{+}, \mathrm{C}_{8} \mathrm{H}_{5} \mathrm{O}_{3}{ }^{+}, \mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{2}{ }^{+}\right.$, $\mathrm{C}_{5} \mathrm{H}_{8} \mathrm{O}_{2}{ }^{+}, \mathrm{C}_{5} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{+}$, and $\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}^{+}$require 167.0344, 150.0317, $149.0239,122.0368,100.0524,95.0133$, and 83.0497 respectively). Band (ii) gave a semi-solid gum ( 37 g ) which crystallised from
benzene in citrine prisms, m.p. 129-131 ${ }^{\circ} \mathrm{C}, \boldsymbol{R}_{\mathrm{F}} 0.35$, of (-)-6-(4-hydroxy-3-oxopent-1 $\mathrm{E}-$ enyl)-2H-pyran-2-one (7) (Found: C , $62.0 ; \mathrm{H}, 5.3 \%$; $M$ 194.0571. $\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{O}_{4}$ requires C, $61.85 ; \mathrm{H}$, $5.2 \%$; $M 194.0579$ ); $v_{\text {max }} 3450,3080 \mathrm{w}, 3040 \mathrm{w}, 1720,1690$, $1600,1537,980$, and $812 \mathrm{~cm}^{-1} ; \lambda_{\text {max. }} .240,342 \mathrm{~nm}(\log \varepsilon 4.11$, 4.23). $m / z 194$ (5) 176.0476 (2), 166.0622 (11), 152 (20), 150.0315 (98), 149.0215 (40), 122.0374 (100), $95.0135(36), 94.0416$ (38), and 93.0345 (22) $\left(\mathrm{C}_{10} \mathrm{H}_{8} \mathrm{O}_{3}{ }^{+}, \mathrm{C}_{9} \mathrm{H}_{10} \mathrm{O}_{3}{ }^{+}, \mathrm{C}_{8} \mathrm{H}_{6} \mathrm{O}_{3}{ }^{+}, \mathrm{C}_{8} \mathrm{H}_{5} \mathrm{O}_{3}{ }^{+}\right.$, $\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{O}_{2}{ }^{+}, \mathrm{C}_{5} \mathrm{H}_{3} \mathrm{O}_{2}^{+}, \mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}^{+}$, and $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{+}$require 176.0473, $166.0630,150.0317,149.0239,122.0368,95.0133,94.0419$, and 93.0340 respectively); $[\alpha]_{589}{ }^{20}-9^{\circ},[\alpha]_{546}{ }^{20}-14^{\circ},[\alpha]_{436}{ }^{20}$ $-83^{\circ}(c, 0.0915)$.

Although the dihydropyrone (2) gave only one spot on analytical t.l.c., p.l.c., particularly in bench (AnalaR) chloroform resulted both in isomerisation to the pent-1 $E$-enyl compound (4) and in the formation of the pyrone (7), $R_{F} 0.35$. Yields were not reproducible, but in one such experiment the dihydropyrone (2) ( 224 mg ) gave the isomer (4) ( 147 mg ) and the crude pyrone (7) $(50 \mathrm{mg})$. The ( $1 E$ )-isomer (4) was a gum $R_{\mathrm{F}} 0.45$ characterised by the ${ }^{1} \mathrm{H}$ n.m.r. spectrum (Table 1). The i.r. spectrum (film) was identical with that of the ( $1 Z$ )-isomer (2).

Further elution of the column with benzene-methanol ( $100: 1,100 \mathrm{ml} ; 50: 1,200 \mathrm{ml}$; and $20: 1,100 \mathrm{ml}$ ) gave intractable gums (total 84 mg ) but benzene-methanol ( $20: 1,100 \mathrm{ml}$ ) then furnished a resin ( 196 mg ) which crystallised from benzene in felted needles, m.p. $93-95^{\circ} \mathrm{C}\left(138 \mathrm{mg}, 35 \mathrm{mgl}^{-1}\right)$. Recrystallisation from ethyl acetate afforded ( $5 \mathrm{~S}, 6 \mathrm{~S}$ )-5,6-dihydro-6-[(3S,4S)-3,4-dihydroxypent-1E-enyl]-5-(2-methylbut-2E-enoyl-oxy)-2H-pyran-2-one (3a) (phomopsolide B) as felted needles, m.p. $97^{\circ} \mathrm{C}, R_{\mathrm{F}} 0.19$ (Found: C, 60.9; H, $6.8 \%, M \mathrm{H}^{+} 297$. $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{O}_{6}$ requires C, 60.8; $\mathrm{H} \mathrm{6.8} \mathrm{\%}$; $\mathrm{M}_{2} 296$ ); $\mathrm{v}_{\text {max. }} 3555,3340 \mathrm{br}$, $1725,1710,1650,1625,990,828$, and $733 \mathrm{~cm}^{-1} ; v_{\text {max. }}\left(\mathrm{CHCl}_{3}\right)$ $1728,1710 \mathrm{~cm}^{-1}$. End absorption in u.v., $\varepsilon 18000$ at 210 nm ; $[\alpha]_{\mathrm{D}}{ }^{20}+250^{\circ}(c, 0.202)$; c.d., $\lambda 214,264 \mathrm{~nm} ; \Delta \varepsilon 35.9,1.41 ; m / z$ 179 (35), 169 (12), 152.0458 (65), 151.0380 (55), 134.0361 (22), 123.0432 (22), 107.0493 (38), 95.0118 (35), and 83.0517 (100) $\left(\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{O}_{3}{ }^{+}, \quad \mathrm{C}_{8} \mathrm{H}_{7} \mathrm{O}_{3}{ }^{+}, \mathrm{C}_{8} \mathrm{H}_{6} \mathrm{O}_{2}{ }^{+}, \quad \mathrm{C}_{7} \mathrm{H}_{7} \mathrm{O}_{2}{ }^{+}, \quad \mathrm{C}_{7} \mathrm{H}_{7} \mathrm{O}^{+}\right.$, $\mathrm{C}_{5} \mathrm{H}_{3} \mathrm{O}_{2}{ }^{+}$, and $\mathrm{C}_{5} \mathrm{H}_{7} \mathrm{O}^{+}$require $152.0473,151.0395,134.0368$, 123.0446, 107.0487, 95.0133 , and 83.0497 respectively). It was recovered unchanged after stirring in AnalaR chloroform for 24 $h$ at room temperature with silica gel 7739 .

The diacetate ( $\mathbf{3 b}$ ), prepared in pyridine with acetic anhydride during 3 days at room temperature, was a gum $R_{\mathrm{F}} 0.64$ (Found: $\mathrm{C}, 60.0, \mathrm{H}, 5.9 \% \mathrm{C}_{19} \mathrm{H}_{24} \mathrm{O}_{8}$ requires $\mathrm{C}, 60.0 ; \mathrm{H}, 6.4 \%$ ); $v_{\text {max. }}$. (film) OH absent; $1720,1709,1645,825$, and $735 \mathrm{~cm}^{-1}$. The dianisate (3c), prepared in benzene ( 1 ml ), from the diol (3a) ( 15 mg ), anisyl chloride ( 18 mg ), and pyridine ( 30 mg ), during 4 days at room temperature, followed by elution from a column of alumina $(2 \mathrm{~g}$, Woelm, neutral, grade III) with benzene-methanol ( $98: 2$ ), was a gum, $R_{\mathrm{F}} 0.67$ (Found: $M \mathrm{H}^{+} 565 . \mathrm{C}_{31} \mathrm{H}_{32} \mathrm{O}_{10}$ requires $M$ 564); $v_{\text {max. }}$ (film) OH absent; $1710 \mathrm{br}, 1605$, and $1510 ; \lambda_{\text {max. }} 211$, 260 (loge $4.52,4.43$ ); c.d., $\lambda 218,248,268 \mathrm{~nm} ; \Delta \varepsilon+24.7,-6.7$, +5.7 .
B. Surface culture. After elution of oblongolide (1), ${ }^{1}$ further elution of the silica gel column ${ }^{1}$ with benzene-methanol ( $100: 1$ ) gave gums ( $150 \mathrm{ml}, 18 \mathrm{mg}$ ) followed by a yellow oil ( $100 \mathrm{ml}, 153$ $\mathrm{mg}, 13.8 \mathrm{mgl}^{-1}$ ) identified by its i.r. and ${ }^{1} \mathrm{H}$ n.m.r. spectra as phomopsolide A (2). After intractable gums ( 60 mg ) had been eluted with benzene-methanol $(50: 1 ; 200 \mathrm{ml})$, benzenemethanol ( $20: 1 ; 100 \mathrm{ml}$ ) furnished a resin ( 79 mg ) which gave phomopsolide B(3a) ( 28 mg ) on crystallisation from benzene followed by ethyl acetate.

Isolation of Phomopsolides A and B from Other Phomopsis Strains.-Column chromatography as described above of the ethyl acetate extract $(2.31 \mathrm{~g})$ of the filtrate from a surface culture on malt extract of the ash strain 123 ( $6.0 \mathrm{l}, 25$ days) gave phomopsolide B(3a) ( $375 \mathrm{mg}, 62.5 \mathrm{mgl}^{-1}$ ); but phomopsolide B
(2) was absent as judged by a careful examination of the eluted fractions by ${ }^{1} \mathrm{H}$ n.m.r. spectroscopy. Likewise a shake culture of the sycamore strain 124 (4.1 1; 21 days) gave phomopsolide B (3a) ( $31 \mathrm{mg}, 7.5 \mathrm{mgl}^{-1}$ ) but no phomopsolide A (2).

Oxidation of the Dihydropyrones (2) and (3a).-A. With chromic oxide (a). Phomopsolide B(3a) ( 15 mg ) in acetone ( 1 ml ) at $0^{\circ} \mathrm{C}$ was treated with the chromic oxide-sulphuric acid reagent ${ }^{12}(50 \mu \mathrm{l})$ during 15 min . After 15 min at room temperature most of the solvent was removed in a stream of $\mathrm{N}_{2}$, and water ( 2 ml ) was added. The resulting emulsion was extracted with ethyl acetate and the organic layer was washed with sodium hydrogen carbonate. On recovery the diketone (5) was obtained as a yellow gum ( 11 mg ), $R_{\mathrm{F}} 0.57$; $v_{\text {max. }}$ (film) OH absent, $3070 \mathrm{w}, 1735,1712,1648,975,830$, and $732 \mathrm{~cm}^{-1}$; $\lambda_{\text {max }}$. 217 nm . Recovery by extraction with chloroform after preparative t.l.c. afforded 6-(3,4-dioxopent-1E-enyl)-2H-pyran-2-one (9) which crystallised from benzene as orange prisms ( 5 mg ), m.p. $155-156{ }^{\circ} \mathrm{C}, R_{\mathrm{F}} 0.52$ (Found: C, $62.5 ; \mathrm{H}, 4.2 \% ; \mathrm{MH}^{+}$ 193. $\mathrm{C}_{10} \mathrm{H}_{8} \mathrm{O}_{4}$ requires $\mathrm{C}, 62.4 ; \mathrm{H}, 4.2 \% ; M 192$ ); $v_{\text {max }} 3090 \mathrm{w}$, $3040 \mathrm{w}, 1732,1710,1680,1622,1580,1565,990,835$, and 808 $\mathrm{cm}^{-1} ; \lambda_{\text {max. }} 243,347 \mathrm{~nm}(\log \varepsilon 3.95,4.13)$ ) $m / z 192(5), 164$ (10), 150 (98), 149 (100), 122 ( 90 ), 121 (30), 95 (70), and 93 (85).

On one occasion when the oxidation was incomplete 6-(3-hydroxy-4-oxopent-1 E-enyl)-2H-pyran-2-one (8) was also obtained as prisms from benzene-light petroleum, m.p. 114 $115^{\circ} \mathrm{C}, R_{\mathrm{F}} 0.47$ (Found: $M \mathrm{H}^{+} 195 . \mathrm{C}_{10} \mathrm{H}_{10} \mathrm{O}_{4}$ requires $M$ 194); $v_{\text {max. }} 3400 \mathrm{br}, 3100 \mathrm{w}, 3060 \mathrm{w}, 1730,1662,1595,1530,970$, and $800 \mathrm{~cm}^{-1} ; \lambda_{\text {max. }} 233,332 \mathrm{~nm}(\log \varepsilon 4.15,4.17)$; $[\alpha]_{589-436}^{\mathrm{D}} 0^{\circ}$; $m / z 150(85), 122(75), 121$ (52), 95 (100), and 94 (90).
(b) Phomopsolide A (2) $(9 \mathrm{mg})$ was oxidised as described above with the same reagent $(20 \mu$ ). The i.r. spectrum of the yellow gummy product ( 5 mg ), $R_{\mathrm{F}} 0.57$, was indistinguishable from that of the diketone (5), and preparative t.l.c. furnished prisms, m.p. $152-155^{\circ} \mathrm{C}, R_{\mathrm{F}} 0.52$, of the pyrone (9).
B. With sodium periodate. Sodium metaperiodate $(5 \% ; 1 \mathrm{ml})$ was added to phomopsolide $\mathrm{B}(\mathbf{3 a})(15 \mathrm{mg})$ in methanol $(0.5 \mathrm{ml})$ and water $(0.5 \mathrm{ml})$ at room temperature. A slow stream of $\mathrm{N}_{2}$ was passed through the reaction mixture and into a trap containing 2,4 -dinitrophenylhydrazine in 2 m -hydrochloric acid. After 2 h the precipitate was collected, dried and recrystallised from ethanol, giving acetaldehyde 2,4-dinitrophenylhydrazone $(4 \mathrm{mg}), R_{\mathrm{F}} 0.70$, m.p. and mixed m.p. with an authentic specimen $158-160^{\circ} \mathrm{C}$. After standing 18 h at room temperature the reaction mixture had deposited needles ( 3 mg ), m.p. $89-90^{\circ} \mathrm{C}$ of 6-(3-oxoprop-1E-enyl)-5(2-methylbut-2E-enoyloxy)-5,6-dihydro- $2 \mathrm{H}-$ pyran-2-one (6) (Found: $\mathrm{C}, 62.5 ; \mathrm{H}, 5.6 \% ; M \mathrm{H}^{+} 251$. $\mathrm{C}_{13} \mathrm{H}_{14} \mathrm{O}_{5}$ requires C, $62.4 ; \mathrm{H}, 5.6 \% ; M 250$ ); $v_{\text {max. }} 3100 \mathrm{w}$, $3060 \mathrm{w}, 1730,1705,1678,1630,972,830$, and $730 \mathrm{~cm}^{-1} ; \lambda_{\text {max }}$. $220 \mathrm{~nm}(\log \varepsilon 4.32) ; m / z 166$ (12), 151 (33), 150 (30), 122 (20), 100 (40), 95 (42), 94 (35), and 83 (100).

Oxidation of the Pyrone (7)- A. With chromic oxide. The pyrone ( 5 mg ) in acetone $(0.5 \mathrm{ml})$ at $0^{\circ} \mathrm{C}$ was oxidised with the chromic oxide-sulphuric acid reagent $(15 \mu l)$ as described above. On the addition of water the product separated as needles (2 mg ), m.p. $155-156^{\circ} \mathrm{C}$ of the pyrone (9), identified by the i.r. spectrum.
B. With sodium periodate. The pyrone ( 2 mg ) was oxidised as described above but in a stoppered tube at room temperature. After 24 h a stream of $\mathrm{N}_{2}$ was passed through the reaction mixture which was kept at $60-70^{\circ} \mathrm{C}$ for 20 min . A small precipitate of acetaldehyde 2,4-dinitrophenylhydrazone, $\boldsymbol{R}_{\mathrm{F}}$ 0.70 , was collected from the trap and was identified as described above. The cooled reaction mixture was extracted with ethyl acetate. Recovery afforded 3-(6-oxo-6H-pyran-2-yl)prop-1Eenoic acid (10) as prisms, m.p. 204-207 ${ }^{\circ} \mathrm{C}$ (decomp.) $R_{\mathrm{F}} 0.06$ (Found: $M$ 166.0266. $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{O}_{4}$ requires $M$ 166.0266); $v_{\text {max. }}$
$3200-2400 \mathrm{br}, 3100 \mathrm{w}, 3050 \mathrm{w}, 1710,1680 \mathrm{br}, 1595,1535$, 985,810 , and $670 \mathrm{~cm}^{-1} ; \lambda_{\text {max. }} 227,330 \mathrm{~nm}(\log \varepsilon 4.29,4.28) ; m / z$ 166 (35), 138 (100), 121 (15), 95 (70), and 94 (32).

Hydrolysis of Phomopsolide B(3a).-The dihydropyrone (15 mg ) in 0.1 N -sodium hydroxide ( 2.00 ml ) was left for 24 h at room temperature. Back titration to pH 6 with 0.1 m -hydrochloric acid $(1.05 \mathrm{ml}, 2$ equiv. acid liberated), followed by extraction with ethyl acetate gave a small ( 1 mg ) intractable neutral fraction. The aqueous layer was acidified to pH 3 with concentrated hydrochloric acid and re-extracted with ethyl acetate. The recovered acid fraction ( 4 mg ) showed only one $\operatorname{spot}\left(R_{\mathrm{F}} 0.45\right)$ in t.l.c. and crystallised from benzene in prisms, m.p. $61-63^{\circ} \mathrm{C}$ (lit., $64^{\circ} \mathrm{C}$ ) of tiglic acid, identified by the i.r. spectrum; $v_{\text {max. }}$ $3500-2500 \mathrm{br}, 1690,1645,790$, and $740 \mathrm{~cm}^{-1}$.
