#### Abstract

Reactions of substituted 1,2,3-triazolium-1-imide 1,3-dipoles with a range of substituted alkene and alkyne dipolarophiles gave rise to derivatives of the new ring systems hexahydropyrrolo [2,3-d]-1,2,3triazoles and the azapropellanes tetra-aza-tricyclo[5.3.3.0 ${ }^{1.7}$ ]tridecenes and -tricyclo[4.3.3.0 ${ }^{1.6}$ ]dodecenes. The reactions, which are regio- and stereo-specific, are shown to be tandem 1,3-dipolar (endo) cycloadditions and sigmatropic rearrangements. X-Ray crystal structures of 6exo-ethoxycarbonyl-2,3a,4,6a-tetraphenyl-3,3a,4,5,6,6a-hexahydropyrrolo[2,3-d]-1,2,3-triazol-2-ium-3ide (9a) and 12exo-cyano-8,10-diphenyl-7,8,9,10-tetra-azatricyclo[4.3.3.0 ${ }^{1.6}$ ] dodec-7-en-8-ium-9ide (4a; $m=2$ ) are reported.

Substituted ( $Z$ )-bis(areneazo)ethylenes ( $\mathbf{1 A}$ ) exist in equilibrium with a cyclic 1,2,3-triazolium-1-imide form (2). ${ }^{1}$ This latter form is a reactive 1,3 -dipole which dominates the reactivity of these systems. ${ }^{2-5}$ Cycloaddition reactions of these 1,3 -dipoles with alkene dipolarophiles gave derivatives of a new pyrrolo[2,3-d]-$1,2,3$-triazole ring system ${ }^{6}$ in a general reaction which is established herein ${ }^{6}$ as involving a tandem 1,3-dipolar cycloaddition and sigmatropic rearrangement. When 1,2 -bis(areneazo)cycloalkenes (1B) were used in these reactions interesting new tricyclic azapropellanes were obtained from the same reaction sequence.

## Results and Discussion

(i) Cycloaddition Products: New Ring Systems.-When compounds (1B; $m=2,3$ ) were treated with acrylonitrile or ethyl acrylate in acetone the products $(4 ; m=2,3)$ and $(5 ; m=2,3)$ were obtained in high yield (Table 1). These products arose from the triazolium 1,3-dipole form (3) and when this azolium dipole could not be formed because of structural strain preventing cyclisation in (1B) [i.e., for $m=1$ or 0$]^{1}$ no reaction occurred and no trace of products such as (4) or (5) was detected. The products (4) and (5) are new azapropellanes, the first examples of tetra-azatricyclo-[4.3.3.0 ${ }^{1.6}$ ]dodecenes $(m=2)$ and -[5.3.3.0 $\left.0^{1,7}\right]$ tridecenes $(m=3)$. They are obviously the end products of a multi-step reaction. Key signals in the carbon NMR spectra which readily indicate their formation are those of the quaternary bridgehead carbons at $\delta_{\mathrm{C}} 80-110$. Figures 1 and 2 show the X-ray crystal structures of compounds (4a; $m=$ 2) and (9a). Their formation is regiospecific and the substituent Z is in the exo-position. The products (6) and (7) were formed when dimethyl acetylenedicarboxylate (DMAD) and $N$-phenylmaleimide were used as dipolarophile, respectively (Scheme 1). The basic structural unit of compounds (4)-(7) is a new, reduced, fused aziminoazapentalene ${ }^{7}$ ring system, a substituted 3,3a,4,5,6,6a-hexahydropyrrolo[2,3-d]-1,2,3-triazole

All of the derivatives show the characteristic bridgehead carbon signals (Scheme 1). When the substrate was a 1,2-

Figure 1. X-Ray molecular structure of compound (4a; $m=2$ ).
bis(arylazo)stilbene (1A) the products (8)-(12) were formed via the dipole form (2). These products contain the basic pyrrolo[2,3-d]-1,2,3-triazole structure but without the continuous tricyclic link between the bridgeheads. Some of these latter products were described previously ${ }^{5}$ but with the wrong structure since the complexity of the tandem reaction was not then understood ( $c f$. ref. 6).
(ii) Stereospecificity.-Dimethyl maleate and dimethyl fumarate were used as probes of the stereospecificity of the reaction. The dipoles (2a) (Scheme 2) and (3c) (Scheme 3) were heated with these dipolarophiles in acetone and the products were worked up carefully. Repeated runs gave isolated yields of the products (13)-(16) (Schemes 2 and 3) (Table 1) in the range $81-96 \%$ and the remaining residues were recovered and analysed by high-field NMR spectroscopy. The reactions were stereospecific ( $>99 \%$ ) and no traces of mixtures were found.

Figure 2. X-Ray molecular structure of compound (9a).

These would have been easy to identify because of the availability of clear-cut NMR signals. The product pairs (13),(14) and (15),(16) were readily identified as cis- and transisomers from the dihedral coupling constant $J\left(\mathrm{H}_{\mathrm{A}}-\mathrm{H}_{\mathrm{B}}\right)$ (Schemes 2 and 3). Further, the molecules (13) and (15) provided models for the endo $-\mathrm{H}_{\mathrm{A}}$ and $-\mathrm{H}_{\mathrm{B}}$ in these systems and therefore allowed a full identification of compounds (14) and
(16) from the other possible trans-isomeric structures with $\mathrm{H}_{\mathrm{A}}$ exo and $\mathrm{H}_{\mathrm{B}}$ endo.

The reaction can be looked upon as a tandem, concerted 1,3dipolar cycloaddition and $1,4-\mathrm{N} \rightarrow \mathrm{C}$ sigmatropic rearrangement (Scheme 4). However, it could also be a multistep Michael reaction involving initial nucleophilic addition of the exocyclic $-\mathrm{N}^{-}$-terminal of the dipole (which is nucleophilic ${ }^{2}$ ) to the alkene giving a new $\mathrm{N}-\mathrm{C}$ single bond followed by subsequent ring closure and cleavage of the $\mathrm{N}-\mathrm{N}$ bond to give a second intermediate. Perusal of such a mechanism shows that it necessitates a loss of stereochemistry due to rotations on the single bonds in a number of intermediates which, because of the substituents, should be sufficiently long-lived for a bond rotation. The stereospecificity ${ }^{8}$ of the reaction therefore favours a tandem, concerted 1,3-dipolar cycloaddition-sigmatropic rearrangement reaction (Scheme 4). The exo-arrangement of substituents in the products (4)-(11) requires an initial endocycloaddition. Dreiding models show that a subsequent $\mathrm{N} \rightarrow \mathrm{C}$ sigmatropic rearrangement will result in a final exo-orientation for the substituents.
(iii) Kinetics and Mechanism.-The kinetics of the reaction for the dipole ( $2 a$ a) with acrylonitrile and ( $E$ )-cinnamaldehyde were measured by following the disappearance of the dipole at a suitable UV wavelength. The synthetic reaction with $(E)$ cinnamaldehyde (reported in the following paper) followed the same pattern but occurred on the $\mathrm{C}=\mathrm{O}$ bond in a rare case. If any of these reactions was likely to be a nucleophilic addition this case with a carbonyl group was considered to be the most likely. The rates were measured under pseudo-first-order conditions with a large excess of alkene and second-order rate constants were also determined (Table 2). The reactions were second order overall and first order in each reagent. Arrhenius measurements gave high negative entropies for both reactions (Table 2), consistent with a cycloaddition transition state. More

Scheme 1. Reagents: i, acrylonitrile (AN); ii, DMAD; iii, EA; iv, maleic anhydride (MA); v, $N$-phenylmaleimide PMI. Ar: (a) Ph ; (b) $p$ - $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Br}$; (c) $p$ $\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{NO}_{2}$; (d) $p-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me} .{ }^{13} \mathrm{C}$ NMR shifts $\left(\mathrm{CDCl}_{3}\right)$ are shown.
significantly the reactions were quite insensitive to solvent polarity and showed a slight decrease in rate for increasing solvent polarity from benzene to ethyl acetate and aliphatic ketones (Table 3). This insensitivity to solvent was similar for the reactions with acrylonitrile and ( $E$ )-cinnamaldehyde as dipolarophiles. Hence both reactions are likely to have similar rate-determining steps which we suggest are non-synchronous, ${ }^{9}$ pericyclic, $6 \pi$-cycloadditions. Somewhat increased rates were observed when chloroform was used as solvent. Increased rates in chlorinated solvents have also been observed with some other cycloadditions, for example that between anthracene and tetracyanoethylene. ${ }^{10}$ These kinetic results, combined with the stereospecificity of the reaction, strongly support the tandem 1,3-dipolar cycloaddition-rearrangement mechanism in Scheme 4.
Some preliminary substituent effects were measured for parasubstituents ( $\mathrm{Me}, \mathrm{Br}, \mathrm{NO}_{2}$ ) in the $N$-Ar ring of the dipole (2) with acrylonitrile as dipolarophile (Table 3). The data were limited due to difficulties with $p$-MeO derivatives which could not be measured. The four points involved (using $\sigma_{p}{ }^{-}$for $\mathrm{NO}_{2}$ ) would give a crude Hammett $\rho$-value of $-1.4(r 0.982)$. Of significance is the reduction in rate by electron-withdrawing groups which is expected for normal electron-demand dipole-HOMO-controlled reactions. ${ }^{11}$ The dipole (2) contains an electron-rich azomethine imide structure and would be expected to give dipole-HOMO-controlled reactions. ${ }^{12}$ For such a transition state the endo-orientation of substituents containing $\pi$-bonds
could readily arise due to favourable secondary orbital interactions or due to a favourable opposed alignment of dipoles. Hence we suggest a rate-determining endo-transition state as is shown in Figure 3, followed by a rapid sigmatropic rearrangment in the tandem reaction.

## Experimental

M.p.s were measured on an Electrothermal apparatus and are uncorrected. IR spectra were measured with a Perkin-Elmer 983G spectrophotometer. NMR spectra were measured on JEOL JNM-GK-270 and MH-100 instruments with tetramethylsilane as internal reference and deuteriochloroform or hexadeuteriodimethyl sulphoxide as solvent. UV-visible absorption spectra were measured with a Shimadzu UV-260 Spectrophotometer. The substrates (2) and (3) were prepared by oxidation of the bishydrazones of the corresponding $1,2-$ diketones. The bishydrazones were prepared as previously described. ${ }^{1,2,13}$ Those from cycloalkane-1,2-diones were oxidised at ambient temperature with (i) nickel peroxide in dry benzene and/or (ii) lead dioxide in dichloromethane. Insoluble salts were removed, the solutions were evaporated, and the residual products (3) were recrystallised. Details have been reported ${ }^{1,2}$ for all of the substrates (3). The bis-arylhydrazones of benzil were oxidised by either of these procedures and also by lead tetra-acetate in acetic acid to give the 1,2-bis(arylazo)stilbenes $(\mathbf{1 A}) /(\mathbf{2})$, some of which are already known. ${ }^{3,4}$

Careful work-up of filtrates show further small quantities of compound (15) not included in the quoted yield. No isomers were detected.
II. Substituted Pyrrolo[2,3-d]-1,2,3-triazoles.-(a) (No.18, Table 1). A solution of 1,2 -bis $(p$-bromophenylazo)stilbene $(\mathbf{1 A b}) /(\mathbf{2 b})(546 \mathrm{mg})$ in dry acetone $\left(10 \mathrm{~cm}^{3}\right)$ was treated with acrylonitrile ( $1.0 \mathrm{~cm}^{3}$ ) and the mixture was stirred under reflux for 1 h and then evaporated under reduced pressure. Recrystallisation of the residue from ethanol gave 2,4 -bis ( p -bromophenyl)-

6 exo-cyano-3a,6a-diphenyl-3,3a,4,5,6,6a-hexahydropyrrolo[2,3-d]-1,2,3-triazol-2-ium-3-ide (8b) ( $84 \%$ ), m.p. $234{ }^{\circ} \mathrm{C}$ (from EtOH); $v_{\max }($ mull $) 2248 \mathrm{~cm}^{-1}(\mathrm{C} \equiv \mathrm{N}) ; \delta_{\mathbf{H}}\left(\mathrm{CDCl}_{3}\right) 3.90-4.30(3 \mathrm{H}$, $\left.\mathrm{m}, \mathrm{CH}_{2} \mathrm{CHCN}\right), 6.75-7.25(12 \mathrm{H}, \mathrm{m}, \mathrm{ArH}), 7.65(4 \mathrm{H}, \mathrm{m}, \mathrm{ArH})$, and $8.18\left(2 \mathrm{H}, \mathrm{d}, \mathrm{H}_{\text {ortho }}\right.$ of $\left.2-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Br}-p\right) ; \delta_{\mathrm{C}}\left(\mathrm{CDCl}_{3}\right) 41.5,51.5$ (88.4) and 99.9, bridgeheads), $111.8,118.25,118.3,124.4,126.8$, $127.5,127.7,127.8,128.2,128.3,131.55,132.4,136.1,139.0$, and 143.0.
(b) (No. 19, Table 1). Ethyl acrylate ( $1.0 \mathrm{~cm}^{3}$ ) was added to a solution of 1,2 -bis $(p$-nitrophenylazo)stilbene ( $1 \mathbf{A c}$ )/(2c) (478 mg ) in dry ethylmethyl ketone and the mixture was heated under reflux for 2 h , then evaporated under reduced pressure, and the orange oily residue was crystallised from ethanol to give orange crystals of 6 exo-ethoxycarbonyl- $2,4-$ bis(p-nitrophenyl)-3a,6a-diphenyl-3,3a,4,5,6,6a-hexahydropyrrolo [2,3-d]-1,2,3,-
triazol-2-ium-3-ide $(9 \mathrm{c})\left(81 \%\right.$ ), m.p. $229^{\circ} \mathrm{C}$ (from EtOH); $v_{\max }($ mull $) 1727 \mathrm{~cm}^{-1}(\mathrm{C}=\mathrm{O}) ; \delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 0.79(3 \mathrm{H}, \mathrm{s}, \mathrm{Me}), 3.7-$

${ }^{a} R=\left[\Sigma| | F_{\mathrm{o}}-F_{\mathrm{c}}| |\right] / \Sigma\left|F_{\mathrm{o}}\right| . \quad{ }^{b} R_{\mathrm{w}}=\left\{\left[\Sigma w\left(F_{\mathrm{o}}-F_{\mathrm{c}}\right)^{2}\right] /\left[\Sigma_{w}\left(\left|F_{\mathrm{o}}\right|\right)^{2}\right]\right\}^{\frac{1}{2}} ;$ $w=1 /\left[\left(\sigma F_{0}\right)^{2}-0.00082 \cdot F_{0}{ }^{2}\right]$. The transformation (1,0,0/1,1,0/ $-1,-1,1$ ) gives the Niggli cell $a 9.328, b$ 10.911, $c$ 11.452, a $61.61^{\circ}$, $\beta 69.76^{\circ}, \gamma 64.79^{\circ}$.
$\delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 3.37\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CO}_{2} \mathrm{Me}\right), 3.39\left(3 \mathrm{H}, \mathrm{s}, \mathrm{CO}_{2} \mathrm{Me}\right), 4.14(1$ H , d, $J_{\mathrm{AB}} 3.3 \mathrm{~Hz}$, pyrrolidino $\mathrm{CH}_{\mathrm{A}} \mathrm{CH}_{\mathrm{B}} \mathrm{N}$, trans), $5.50(1 \mathrm{H}$, d, pyrrolidino $\mathrm{CH}_{\mathrm{A}} \mathrm{CH}_{\mathrm{B}} \mathrm{N}$, trans), 6.87-7.2 (14 H, m, ArH), 7.5$7.58(4 \mathrm{H}, \mathrm{m}, \mathrm{ArH}), 8.3\left(2 \mathrm{H}, \mathrm{m}, \mathrm{H}_{\text {ortho }}\right.$ of $\left.2-\mathrm{Ph}\right), \delta_{\mathrm{C}}\left(\mathrm{CDCl}_{3}\right) 52.2$, 52.6, 59.7, 63.9 ( 88.6 and 101.4, bridgeheads), 117.3, 119.0, 123.2, $127.16,127.3,127.7,127.74,128.5,128.7,129.0,131.7,136.6$, $136.64,143.5,171.25$, and 172.4. Careful analysis of the ethanol filtrate showed that no other isomers were present. Full ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR assignments of many of the compounds in Table 1 are provided as Supplementary Publication. SUP 56795 (4 pp.).* Assignments were confirmed by decoupling experiments.
III. Kinetics.-Rates were measured by following the disappearance of the dipole (bis-arylazoalkene) at a chosen wavelength (Tables 2 and 3) using a Pye-Unicam SP1800 double-beam spectrophotometer with water-circulating thermostatted cell compartments. Temperatures were accurate to $\pm 0.5^{\circ} \mathrm{C}$. The dipolarophiles were present in 2000 molar excess for the pseudo-first-order measurements and in the range $1200-$ 200 molar excess for measurements of the second-order rate constants. In a typical run a UV cell containing a fresh stock solution $\left(2.5 \times 10^{-4} \mathrm{M}\right) ; 3.0 \mathrm{~cm}^{3}$ ) of dipole (2) was preequilibrated with the dipolarophile and the falling absorbance, $\left(A_{t}\right)$, was recorded. A plot of $\ln \left(A_{t}-A_{\infty}\right)$ versus $t$ gave a straight line with slope $k_{1}$, the first-order rate constant. For varying (excess) concentrations of the dipolarophile a plot of $\log k_{1}$ versus the dipolarophile concentration gave a straight line with slope $k_{2}$, the second-order rate constant.

[^0]Table 5. Crystal data for compound (9a).

${ }^{a} R=\left[\Sigma| | F_{\mathrm{o}}-F_{\mathrm{c}} \|\right] / \Sigma\left|F_{\mathrm{o}}\right| . \quad{ }^{b} R_{\mathrm{w}}=\left\{\left[\Sigma w\left(F_{\mathrm{o}}-F_{\mathrm{c}}\right)^{2}\right] /\left[\Sigma_{w}\left(\left|F_{\mathrm{o}}\right|\right)^{2}\right]\right\}^{\frac{1}{2}} ;$

IV. $X$-Ray Crystal Data.-The structures of compounds (9a) and ( $4 \mathbf{a} ; m=2$ ) were solved by direct methods and refined by full-matrix least-squares using SHELX76. ${ }^{14}$ Data were corrected for Lorentz and polarisation effects but not for absorption. Hydrogen atoms were included in calculated positions with fixed thermal parameters (0.06). All nonhydrogen atoms were refined anisotropically. The atomic scattering factors for non-hydrogen and hydrogen atoms and the anomalous dispersion correction factors for non-hydrogen atoms were taken from the literature. ${ }^{15-17}$ All calculations were performed on a VAX 8700 computer. The ORTEP program was used to obtain the drawings. ${ }^{18}$ Crystal data for compounds (4a; $m=2)$ and (9a) are given in Tables 4 and 5, and Tables 6 and 7 contain the fractional atomic co-ordinates for these two compounds.*

## Acknowledgements

The following acknowledge Irish Government Maintenance and EOLAS grants for postgraduate research: A. M. E., A. M. G., J. P. J., and E. McN. We thank Dr. M. J. Hynes for advice on the kinetic data.
