Photolysis of steroidal models of oxabicyclic hemiacetals such as 2-oxabicyclo[4.4.0]decan-1-ol, 9-oxabicyclo[4.3.0]nonan-1-ol and 2-oxabicyclo[3.3.0]octan-1-ol, in the presence of (diacetoxy-iodo)benzene and iodine afforded, through ring expansion, ten-, nine- and eight-membered lactones, respectively. Spiro lactones of dihydropyran-5-spirocyclohexan-2(3*H*)-one and dihydrofuran-4-spirocyclohexan-2(3*H*)-one types were obtained by photolysis of steroidal models of 2-oxabicyclo[2.2.2]octan-1-ol and 7-oxabicyclo[3.2.1]octan-1-ol, respectively.

Medium- and large-ring lactones are of interest both with regard to the chemistry of natural products and to the immense pharmacological importance of many macrolide antibiotics containing these groups.¹

A macrolide synthesis inevitably faces two major problems: the formation of the medium- or large-lactone ring and the stereochemical control of the chiral centres fixed on the ring system. This made the ring expansion methodology attractive for the resolution of the aforementioned problems. Although the concept of cleaving fused bonds in bicyclic [*n.m.0*] structures to create large rings has been applied with some success to the synthesis of macrocyclic lactones,² the scope of the concept has by no means been fully explored.

Continuing our studies on the synthetic applications of the β -fragmentation of alkoxy radicals generated from cyclic alcohols by reaction with hypervalent iodo compounds,³ we describe in detail the β -fragmentation of alkoxy radicals generated from oxabicyclic hemiacetals of [*n.m.0*], [2.2.2] and [3.2.1] types, in order to achieve, through ring opening, the synthesis of medium-sized lactones as well as spiro lactones. Other syntheses of lactones by oxidative ring expansion fragmentation reactions have been reported^{4,5} while our work was underway or after publication of our preliminary communication.^{6a}

The different types of starting materials and the expected β -fragmentation products are outlined in Scheme 1. The reaction has been studied on steroidal models with special attention being paid to the regioselectivity of the process. Preliminary results to ascertain the feasibility of this approach have been reported earlier.⁶

Results and Discussion

Fragmentation of Oxabicycles [*n.m.0*].—The β -fragmentations were expected to occur through the mechanism shown in Scheme 1. Models **1** and **2** were selected because in the ring-chain tautomerism of the keto alcohols, the hemiacetal form (five- and six-membered rings)⁷ is preferred. Moreover, the stability of the C-radical **A** (R = Me) will be favoured, which should be important in the regioselectivity of the ring opening process. The model compound **22** was prepared in order to study during the fragmentation the formation of a secondary *versus* a primary C-radical intermediate **A** (R = H) and to see how this influenced the regioselectivity.

Steroidal models **1** and **2** were prepared from the known keto acids **3**⁸ and **5**⁹ as follows. Methylation of the latter gave

esters **4** and **6** which were treated with ethylene glycol and catalytic amounts of PTSA (toluene-*p*-sulphonic acid) to afford the ethylenedioxy derivatives **7** and **9**. These compounds were then reduced with LAH (lithium aluminium hydride) to give the alcohols **8** and **10** which after hydrolysis gave the hemiacetals **1** and **2**,¹⁰ respectively.

In the case of the hemiacetal **1** the spectroscopic data (see Experimental section) indicate that the ring-chain tautomerism between the hydroxy ketone and the cyclic hemiacetal is strongly displaced to the ring form. On the other hand, the complex ¹³C NMR spectrum displayed by hemiacetal **2** indicates a slow equilibrium between the tautomers.¹¹

The reaction of hemiacetals **1** and **2** with (diacetoxyiodo)-benzene (DIB) in the presence of iodine was performed by photolysis, after careful deoxygenation, with visible light (2 × 100 W tungsten-filament lamps) in cyclohexane under the conditions summarized in Table 1 (entries 1–4). The reaction gave good yields (*ca.* 80%) of medium-sized lactones when approximately stoichiometric amounts of DIB and iodine were used (entries 1 and 4). The presence of iodine was shown to be necessary for the reaction to take place (entry 2). When a catalytic amount of iodine was used only 30% of the hemiacetal was transformed after 2 h at 40 °C (entry 3).

The structures of lactones **11**–**15** were determined on the basis of spectral evidence. Lactone **11** shows in its ¹H NMR spectrum broad signals for 19-H and 2-H, and its ¹³C NMR spectrum is also complex due to the slow conformational equilibrium of the nine-membered ring lactone. A similar situation is observed for the NMR spectra of lactone **13**, in contrast with the neat and well resolved NMR spectra observed for lactones **12**, **14** and **15**.

The stereochemistries of the double bonds in lactones **14** and **15** were determined as *Z* and *E*, respectively, as deduced from the observed shielding of the C-10 methyl group signals in their ¹³C NMR spectra (18.70 ppm for **14** and 13.14 ppm for **15**).¹² Recently, Sugimoto *et al.*^{5b} have published details of the fragmentation of the hemiacetal **2** upon irradiation with a 100 W high pressure mercury lamp in benzene containing mercury(II) oxide and iodine, to give lactones **14** and **15** as the sole products.

The steroidal model of 2-oxabicyclo[3.3.0]octan-1-ol was prepared starting from the known lactone **16**¹³ which was methylated to give **17** and reduced with LAH to afford diol **18**. Partial acetylation of **18** gave monoacetate **19** which was oxidized with an excess of Jones' reagent to give the ketone **21**. Hydrolysis of **21** provided the required hemiacetal **22**. This

compound was in equilibrium with the open form, as shown by the complex ^1H and ^{13}C NMR spectra observed. Further characterization was achieved by means of the methyl acetal **23**, as shown in the Experimental section.

The photolysis of the hemiacetal **22** was realized analogously, as indicated in Table 1 (entry 5), to give the iodo lactone **24** as a single stereoisomer. AM parts of AMX systems were observed for 15-H and 22-H in its ^1H NMR spectrum, and the signal for the methine proton at C-17 appears as a singlet at 3.92 ppm. The structure and stereochemistry of the eight-membered

lactone **24** was determined by X-ray crystallographic analysis (Fig. 1). The radical intermediate at C-17 is trapped by an iodo radical in a stereoselective manner to give an iodo derivative with *R* stereochemistry.

In the three models studied, **1**, **2** and **22**, β -fragmentation takes place with total regioselectivity to cleave the more substituted bond, in every case.

Fragmentation of [2.2.2] Oxabicycles.—A steroidal model of 2-oxabicyclo[2.2.2]octan-1-ol **31** was obtained starting from the known bromo ether **26**¹⁴ essentially following reactions described in other steroid series.¹⁵ Oxidation of the 3β -alcohol with Jones' reagent led to the ketone **27** which was reduced with Zn dust in acetic acid to give the enone **28**. After protection of the primary alcohol by reaction with dihydropyran, the

resulting tetrahydropyranyl (THP) ether **29** was reduced with lithium in liquid ammonia to the ketone **30**. Cleavage of the THP ether afforded the desired hemiacetal **31**.¹⁶

The photolysis of the oxabicyclo **31** under the conditions shown in Table 1 (entry 6) afforded a mixture of the regioisomeric iodo lactones **32** and **33**. The structures of both compounds were established by spectroscopic means. The ¹³C NMR spectra of **32** and **33** show the carbon bearing the iodine atom at 10.28 and –3.5 ppm, respectively. Additional proof of these structures came from their ¹H NMR spectra (see Experimental section). The observed long range coupling (W coupling) between protons 5 α and 19 α in the ¹H NMR spectrum of lactone **33** confirms its structure.

These lactones may be synthetically useful since both types are present in the structure of important natural products. For instance, the formation of the spiro lactone **32** is the key step in

the synthesis of limonin,¹⁷ and the main structural features of the sesquiterpene vernolepin¹⁸ are present in the lactone **33**.

In order to improve the regioselectivity of the reaction two other related models of 2-oxabicyclo[2.2.2]octan-1-ol, the hemiacetals **35** and **39**, were prepared. Methylation of the enone **29** with methyl iodide and potassium *tert*-butoxide afforded the dimethyl ketone **34** and subsequent hydrolysis of the THP ether gave the hemiacetal **35**.^{17a} Formation of the methyl acetal **36**, followed by hydrogenation of the double bond over palladium-on-carbon, after hydrolysis, the hemiacetal **39**. The observed stereoselectivity in the hydrogenation arises from the strong steric hindrance produced by the methyl acetal group on the β -face of the molecule.^{17a}

Photolysis of the hemiacetals **35** and **39** with DIB and iodine gave, under the conditions and in the yields shown in Table 1 (entries 7 and 8), the corresponding spiro lactones **37** and **40**.

An analogue of the hemiacetal **39** has been transformed into the lactone **40** during the synthesis of rings A and A' of limonin^{17b} in several steps and low overall yield, using a Beckmann fragmentation for ring cleavage.

Fragmentation of [3.2.1] Oxabicycles.—The synthesis of the steroidal models of the 7-oxabicyclo[3.2.1]octan-1-ol **49** and **51** was realized as follows: the known 3-oxocholestane-5 α - and -5 β -carbonitrile **41** and **42**¹⁹ were reduced, after protection of the carbonyl group, with diisobutylaluminium hydride in toluene, to afford the aldehydes **45** and **46**; further reduction with LAH and deprotection gave the desired isomeric hemiacetals **49** and **51**, respectively.

Fragmentation of these hemiacetals promoted by DIB and iodine (Table 1, entries 9 and 10) gave the iodo spiro- γ -lactones **50** and **52**. The structures were confirmed by NMR spectroscopy, the iodine-bearing carbon appearing at 1.99 ppm in the ¹³C NMR spectrum of **50** and at 2.19 ppm in that of **52**. The stereochemistry at C-5 was confirmed by nuclear Overhauser effect (NOE) spectroscopy. Thus irradiation of 10-Me methyl group resulted in a strong enhancement of the AB system at C-4 in lactone **50** and of that at C-1' in lactone **52**. Further evidence comes from the long range coupling (J_w 1.4 Hz) between the 6 β -H and the proton 1'-*pro-S* in lactone **50** and the same 6 β -H and the proton 4'-*pro-S* in lactone **52**.

This study of the stereochemistry at C-5 is necessary because the stereochemistry of the starting cyano ketones has been determined exclusively on the basis of molecular rotations.¹⁹ The fragmentation of these hemiacetals proceeded with total regioselectivity to give the smallest ring lactone. No products arising from the cleavage of the C(2)–C(3) bond have been detected.

We conclude that the use of the hypervalent iodo reagent DIB in the presence of iodine seems to be a good method for the generation and β -fragmentation of alkoxy radicals. The reaction is smooth and proceeds under mild conditions in good yields.

Since our preliminary communication,⁶ we have used hyper-valent iodo compounds as reagents in the β-fragmentation of carbinolamides,^{3b} lactols,^{3c} and unsaturated lactols,^{3a} and some applications of this reaction to the synthesis of natural products have also been published.^{6b,c} This methodology has recently been used by Stork²⁰ and Yamamoto²¹ for the fragmentation of different types of intramolecular hemiacetals.

Crystallographic Data for Compound 24.—A suitable crystal of 0.22 × 0.30 × 0.20 mm³ was selected for X-ray analysis. Cell parameters obtained by least squares analysis of diffractometer measurements of 44 centred reflections with 10 < θ < 45°. The crystals are monoclinic space group P2₁; $a = 11.956(1)$, $b = 12.566(1)$, $c = 7.2900(3)$ Å, $\beta = 96.772(4)^\circ$. Data col-

lected on a Philips PW 1100 four-circle diffractometer with graphite monochromated Cu-K α radiation, $\omega/2\theta$ scan technique, scan speed 0.055° s⁻¹, scan width 1.50°, θ_{\max} 65°. Two standard reflections (2 2 0, –2 –2 0) measured every 90 min showed no variation in the intensity. 1959 Independent reflections were measured, 1825 observed [$I > 2\sigma(I)$]. Corrections of Lorentz and polarization were applied. The structure was solved by Patterson and direct methods (MULTAN).²³ An absorption correction ($\mu = 118.257 \text{ cm}^{-1}$) following the DIFABS²⁴ procedure was applied on isotropically refined data. Full-matrix least-squares anisotropic refinement (on F) of all non-hydrogen atoms and subsequent difference Fourier synthesis revealed positions for all H atoms; they were included in the last cycles of refinement as fixed contributors. Neutral-atom scattering factors and anomalous dispersion corrections were taken from International Tables of Crystallography.²⁵ A weighting scheme was applied so as not to give trends in $\langle w\Delta^2 F \rangle$ vs. $\langle F_0 \rangle$ and vs. $\langle \sin \theta/\lambda \rangle$. Final R and R_w values are 6.7 and 8.7, respectively. The non-hydrogen atom numbering is shown in the molecular projection (Fig. 1); the more significant results (non-H co-ordinates, bond lengths and angles) are given in Tables 2–4. Full lists of bond lengths and angles, hydrogen coordinates and anisotropic thermal parameters have been deposited at the C.C.D.C.*

19-Hydroxycholest-4-en-3-one 28.—The alcohol **25** (500 mg) in acetone (100 cm³) at 0 °C was treated dropwise with Jones' reagent until permanently orange in colour; the excess of reagent was then destroyed by adding methanol. The mixture was poured into water and extracted with diethyl ether, which was washed with water, dried (Na₂SO₄) and evaporated under reduced pressure to give the unstable ketone **27** which was used in the next step without purification.

The crude ketone **27** in propan-2-ol (30 cm³) and acetic acid (3.4 cm³) was stirred and heated at 80–90 °C for 3 h with zinc dust (3.2 g, previously activated by brief washing with 5% hydrochloric acid, water, methanol, and diethyl ether). The filtered solution was then poured into water and extracted with chloroform, which was washed with saturated aqueous NaHCO₃ and brine, dried (Na₂SO₄) and concentrated under

dried (Na₂SO₄) and concentrated under reduced pressure, to give the crude tetrahydropyranyl ether **29** which was used without purification in the next reaction.

A solution of the crude tetrahydropyranyl ether **29** (0.56 g) in anhydrous THF (10 cm³) was added with stirring to a solution of lithium (60 mg) in distilled liquid ammonia (20 cm³). After 10 min the lithium excess was destroyed with solid ammonium chloride. The residue obtained after evaporation of the ammonia was treated with water and the resulting mixture was extracted with ethyl acetate, and the extract was washed with brine, dried (Na₂SO₄) and evaporated under reduced pressure. The residue was stirred in dioxane containing hydrochloric acid (0.5 mol dm⁻³; 5 cm³) for 24 h at room temperature. The usual processing gave a crude product which was purified by column chromatography (hexane-ethyl acetate; 90:10) to give the *title compound* **31** (420 mg, 83%), m.p. 146–147 °C (hexane-acetone); $[\alpha]_D^{+49}$ (c 0.20); $\nu_{\max}/\text{cm}^{-1}$ 3610–3570, 3500–3200 and 1700; δ_{H} 0.85 (3 H, s, 13-Me), 0.86 (6 H, d, J 6.31, 25-Me₂), 0.89 (3 H, d, J 6.21, 20-Me) and, 4.02 (1 H, m, $W_{1/2}$ 75 Hz, 3-H); δ_{C} complex spectrum due to the ring-chain tautomerism; m/z 402.3475 (30%, M⁺.
