# Synthesis and Properties of Tetrazolium-N-phenacylides. Part $\mathbf{2 1}^{11}$ 

Dietrich Moderhack* and Dirk-Ottfried Bode<br>Institut für Pharmazeutische Chemie der Technischen Universität, D-W-3300 Braunschweig, Germany

Various 1-alkyl-5-methyl-1H-tetrazolium-4-phenacylides 3 (homologues of $\mathbf{C}$ ) have been prepared, acylated and (thio) carbamoylated. The unstable ylide $\mathbf{C}$ has been acylated in situ.

Several years ago we set out to prepare tetrazolium- $N$ phenacylides such as $\mathbf{A}-C .{ }^{1}$ The synthetic route we followed was the general one of Kröhnke, ${ }^{2}$ i.e. treatment of the corresponding tetrazolium salts with an excess of potassium carbonate in the cold. While compounds $\mathbf{A}$ and $\mathbf{B}$ were obtained as reasonably stable solids, the isomer $\mathbf{C}$ was an oil that decomposed on isolation. The instability of the latter is a consequence of poor resonance interaction between the carbanionoid lone pair and the electron-attracting heterocycle. ${ }^{1}$ We subsequently concentrated on higher homologues of $\mathbf{C}$; preliminary experiments ${ }^{3}$ with the tetrazolium salt $\mathbf{2 g}$ (which gave $\mathbf{3 g}$ ) had suggested that ylides of that kind should be less elusive species. This was borne

out by base treatment of various tetrazolium salts e.g. 2c-f, h, i [all provided by phenacylation of the tetrazoles $1(c f$. refs 1 and 4)]. As in the case of $\mathbf{3 g},{ }^{3}$ the respective ylides $\mathbf{3 c}-\mathbf{f}, \mathrm{h}$, i could be easily separated from the reaction mixtures. In addition, the methyltetrazolium salts $\mathbf{2 a}, \mathbf{b}$ having bromo- and nitrosubstituted phenacyl functions proved suitable candidates, while efforts to isolate ylides derived from salts bearing bulkier groups on tetrazole carbon (e.g. $\mathbf{2 k}$ and $\mathbf{2 l}$ ) remained unrewarded.

The ylides 3 are colourless or yellow solids (3b, i). Their stability depends on the $N$-substituent: derivatives having smaller groups began to decompose soon after isolation, their analytical data are therefore only approximate. An essential feature observed throughout is the presence of crystal water which apparently serves to stabilise the negative charge. Attempts to remove the water by drying agents or even handling of the hydrated ylides in aprotic solvents resulted in fast decomposition. ${ }^{3 b}$ On addition of acid, the starting tetrazolium ions in 2 were regenerated. This, in conjunction with the analytical composition found ( 1 mol crystal water), would also hold for a structural unit such as $D(X=Y=N)^{5}$ and a tetrazolium hydroxide ( 2 : OH in place of X ), respectively.

However, spectroscopic evidence is clearly in favour of the phenacylide function: (i) the IR spectra of solid 3, in the range $v$ $1400-1600 \mathrm{~cm}^{-1}$, closely resemble those of the ylides $\mathbf{A}$ and $\mathbf{B}$ which are known to crystallise in anhydrous form; ${ }^{1}$ (ii) the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra exhibit distinct $\overline{\mathrm{C}} \mathrm{H}$ signals (in general $\delta_{\mathrm{H}}$ $6.4-6.5, \delta_{\mathrm{C}} c a .87 .0$ ); these appear at higher field with respect to B $\left(\delta_{\mathrm{H}} 7.2, \delta_{\mathrm{C}} 96.2\right)$, but are in the region of the ylide $\mathbf{A}\left(\delta_{\mathrm{H}} 6.45, \delta_{\mathrm{C}}\right.$ 87.4 ; all spectra taken in MeOH ); (iii) the UV spectra of 3 display an intense absorption at $c a .300 \mathrm{~nm}$ and at 350 nm in the case of the nitro-substituted derivatives [recorded in $\mathrm{NaOH}(0.1$ mol dm ${ }^{-3}$ )]. This matches known values of the iso- $\pi$-electronic moiety $\mathbf{E}(X=N, Y=C M e ; X=C H, Y=N) .{ }^{5 a, 6}$ Since the electron-withdrawing force of the tetrazolium ring in $\mathbf{C}$ is weaker than in $\mathbf{A}$ and $\mathbf{B},{ }^{1}$ the (negative) solvatochromism typical of the 'ylide band' ${ }^{7}$ is more pronounced than with $\mathbf{A}$ and B. This could be demonstrated by using protic solvents of different polarity (see Experimental section: 3c); yet, a full range study of the phenomenon as has been performed with A and B ${ }^{1}$ was vitiated by the sensitivity of 3 towards solvents of aprotic character.

As expected, the ylides 3 show appreciable reactivity towards electrophiles. Treatment of 3 e and 3 g with benzoic anhydride gave the dibenzoylmethylides $\mathbf{4 c}$ and $\mathbf{4 d}$. A congener of this type, viz. a diformylmethylide, has recently been prepared in a different manner and reported to be 'not very stable'. ${ }^{8}$ In contrast, the ylides $\mathbf{4 c}$, $\mathbf{d}$ did not decompose even on prolonged storage. The long wavelength UV absorption of these diacylmethylides lacks the strong (negative) solvatochromism observed with the starting ylides 3 (see Experimental section: 4c). ${ }^{6}$ Phenyl isocyanate and isothiocyanate, respectively, smoothly converted $\mathbf{3 g}$ and 3 into the carbamoylated ylides $\mathbf{4 e}$ and 4 . From 3 g , carbon disulfide and methyl iodide in the presence of base the ketene thioacetal 5 was obtained (cf. refs. $2 c$ and 9). This kind of transformation had failed with the ylides $\mathbf{A}$ and $\mathbf{B}$ because of lack of reactivity. ${ }^{3 b}$ Attempts to alkylate the ylides $\mathbf{3}$, e.g. $\mathbf{3 c}$ or $\mathbf{3 g}$, only left intractable tars.

Since the 'parent' ylide $\mathbf{C}$ is not isolable, it has been treated in situ. Thus, treatment of the salt $\mathbf{2 m}$ with acetic and benzoic anhydrides in the presence of base afforded the stable ylides $4 \mathbf{a}$ and $\mathbf{4 b}$. In the first case, minor quantities of the $1 H$-pyrrolotetrazoles $6 a$ and $6 \mathrm{~b} \dagger$ were separated as byproducts (identified spectroscopically and by comparison with samples obtained from acetic anhydride and the salts $7 \mathbf{a}$ and 7 b , respectively). Structural type and mode of formation of the major component $\mathbf{6 a}$ refer to certain acetylpyrrolo[1,2-a]benzimidazoles ${ }^{10 a}$ and an acetylpyrrolo [2,1-c]-1,2,4-triazole. ${ }^{10 b}$ However, this formal analogy does not include the long known direct synthesis of acetylpyrrolo [2,1-b]thiazoles because in that case also the carbonyl carbon of the phenacyl group is involved in pyrrole ring closing. ${ }^{11}$ Further work on compounds 6 which represent a novel class of aromatic azapentalenes ${ }^{12}$ is in progress.

## Experimental

M.p.s were determined on a Kofler microscope. IR spectra were taken on a Pye-Unicam SP 1100 instrument. ${ }^{1} \mathrm{H}$ NMR spectra were run on a Varian EM-390 instrument (except for the ylides 3 which were measured with a Bruker AM-400 spectrometer). $J$-Values in Hz . ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker AM-400 instrument (tetramethylsilane as internal standard throughout). Mass spectra were determined on a Finnigan MAT 8430 instrument. UV spectra were taken with PyeUnicam SP 8-200 and SP 8-400 spectrophotometers.
Starting 1,5 -dialkyltetrazoles $1 \mathbf{a}^{13}$ and $1 d, \mathbf{f}^{14}$ were made by literature procedures, as were $\mathbf{1 b}, \mathbf{c}, \mathbf{e}$ and $\mathbf{g}$ [yield, b.p. or m.p., $\delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right)$ of $5-\mathrm{Me}$ or $\left.1-\mathrm{Me}\right]\left[1 \mathrm{~b}, 79 \%, 75^{\circ} \mathrm{C}(0.03 \mathrm{Torr})^{*}, 2.60\right.$; $1 \mathrm{c}, 48 \%, 120-121^{\circ} \mathrm{C}(0.1 \mathrm{Torr}), 2.60$; 1e, $29 \%, 88-89^{\circ} \mathrm{C}$ (light petroleum) (lit., ${ }^{15} 82-83^{\circ} \mathrm{C}$ ), $2.66 ; \mathbf{1 g}, 35 \%$, distilled with decomp., 4.0 (quoted $\delta_{\mathrm{H}}$ values in accord with ref. 15].

2-(5-Cyclohexyltetrazol-1-yl)acetophenone 1h. ${ }^{16}$-Anhydrous potassium carbonate ( $34.6 \mathrm{~g}, 0.25 \mathrm{~mol}$ ) was added portionwise to a refluxing solution of 5-cyclohexyltetrazole ${ }^{17}$

[^1]( $76.1 \mathrm{~g}, 0.5 \mathrm{~mol}$ ) [m.p. $130-133^{\circ} \mathrm{C}$ (water) (lit., ${ }^{18} 133-134^{\circ} \mathrm{C}$ )] and 2-bromoacetophenone ( $99.5 \mathrm{~g}, 0.5 \mathrm{~mol}$ ) in acetone ( 500 $\mathrm{cm}^{3}$ ). The boiling mixture was stirred for a further 8 h and then poured into cold water ( $750 \mathrm{~cm}^{3}$ ). The solid formed was filtered off and chromatographed on silica gel. Benzene as the first eluent gave the isomeric 2-(5-cyclohexyltetrazol-2-yl)acetophenone ( $51.1 \mathrm{~g}, 38 \%$ ), m.p. $76-77^{\circ} \mathrm{C}$ (ethyl acetate-light petroleum) (Found: C, 66.8; H, 6.8; N, 20.9. $\mathrm{C}_{15} \mathrm{H}_{18} \mathrm{~N}_{4} \mathrm{O}$ requires $\mathrm{C}, 66.65 ; \mathrm{H}, 6.7 ; \mathrm{N}, 20.7 \%) ; v_{\max }(\mathrm{KBr}) / \mathrm{cm}^{-1} 1710$; $\delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 1.0-2.25\left[10 \mathrm{H}, \mathrm{m}, \mathrm{CH}\left(\mathrm{CH}_{2}\right)_{5}\right], 2.95\left[1 \mathrm{H}, \mathrm{m}_{\mathrm{c}}\right.$, $\left.\mathrm{CH}\left(\mathrm{CH}_{2}\right)_{5}\right], 6.01\left(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2} \mathrm{CO}\right), 7.3-7.6(3 \mathrm{H}, \mathrm{m}, \mathrm{Ph})$ and $7.8-$ $8.0(2 \mathrm{H}, \mathrm{m}, \mathrm{Ph})$. Subsequent elution with ethyl acetate afforded the product $1 \mathrm{~h}(43.0 \mathrm{~g}, 32 \%)$, m.p. $116^{\circ} \mathrm{C}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$-light petroleum) (Found: C, 66.7; H, 6.7; N, 20.7. $\mathrm{C}_{15} \mathrm{H}_{18} \mathrm{~N}_{4} \mathrm{O}$ requires $\mathrm{C}, 66.65 ; \mathrm{H}, 6.7 ; \mathrm{N}, 20.7 \%$ ); $v_{\text {max }}(\mathrm{KBr}) / \mathrm{cm}^{-1} 1705$; $\delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 0.9-2.1\left[10 \mathrm{H}, \mathrm{m}, \mathrm{CH}\left(\mathrm{CH}_{2}\right)_{5}\right], 2.63\left[1 \mathrm{H}, \mathrm{m}_{\mathrm{c}}\right.$, $\left.\mathrm{CH}\left(\mathrm{CH}_{2}\right)_{5}\right], 5.78\left(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2} \mathrm{CO}\right), 7.4-7.7(3 \mathrm{H}, \mathrm{m}, \mathrm{Ph})$ and $7.9-$ 8.1 ( $2 \mathrm{H}, \mathrm{m}, \mathrm{Ph}$ ).

1,4,5-Trisubstituted Tetrazolium Salts 2a-k: General Procedure. ${ }^{3 b, 4}$-A solution of the tetrazole $1(0.01 \mathrm{~mol})$ and (substituted) 2-bromoacetophenone ( 0.011 mol ) in anhydrous nitromethane ( $15-20 \mathrm{~cm}^{3}$ ) was heated to $70-75^{\circ} \mathrm{C}$ for the time indicated. The product was isolated by evaporating the solvent under reduced pressure and crystallising the residue from ethanol-ether. In the case of 2 k , aqueous $\mathrm{HClO}_{4}\left(70 \% ; 50 \mathrm{~cm}^{3}\right)$ was added to the crude bromide dissolved in ethanol; after gentle heating and dilution with water the product was filtered off.

1-Alkyl-5-methyl-1H-tetrazolium-4-phenacylides 3a-i: General Procedure.-Addition of potassium carbonate ( $4.1 \mathrm{~g}, 0.03$ $\mathrm{mol})$ in water $\left(10 \mathrm{~cm}^{3}\right)$ to the tetrazolium salt $2(0.01 \mathrm{~mol})$ in the minimum amount of water at $0^{\circ} \mathrm{C}$ with vigorous stirring gave immediate separation of the products (in the case of oily precipitates, crystallisation occurred on adding a piece of ice). The mixtures were stirred for a further 30 min at $0^{\circ} \mathrm{C}$, after
which the products were filtered off, dried in an air current at ambient temperature and recrystallised from ethanol-water at 0 to $-20^{\circ} \mathrm{C}$ (unless otherwise stated). On storage, even below $0^{\circ} \mathrm{C}$, the products gradually decomposed. The multiplicity (d) of the ylidic carbon was established by ${ }^{1} \mathrm{H}$ off-resonance decoupling (not by means of the DEPT pulse technique otherwise applied in this work). An external ${ }^{2} \mathrm{H}$ lock of $\mathrm{CD}_{3} \mathrm{OD}$ or $\mathrm{C}_{6} \mathrm{D}_{6}$ was used throughout.
