The trans-adduct 8 derived from indene and N,N-dichlorourethane serves as a precursor for the cis1.2 -diaminoindane 6 and the trans-diamines 7 and 14. Conversion of 6 and 14 into the triazabenzocycloheptafluorenes 1 and 2, respectively, via the indenopyrazines $\mathbf{4}$ and $\mathbf{5}$ is described.

The synthesis of conformationally restricted analogues 1 and 2 was undertaken as part ${ }^{1}$ of a programme to investigate the link

$14 \mathrm{a}-\mathrm{H}$ and $12 \mathrm{c}-\mathrm{H}$ cis
$24 \mathrm{a}-\mathrm{H}$ and 12c-H trans

between conformation and biological activity in a series of compounds related to the antidepressant drug mianserin 3.

The problem of constructing the target compounds may be logically reduced to that of obtaining the cis- and transindenopyrazines 4 and 5 , which are in principle accessible from suitably functionalised 1,2-diaminoindanes (Scheme 1). The

Scheme 1
initial task was therefore the stereoselective synthesis of cis and trans vicinal diamines 6 and 7. Although methods are available for setting up vicinal diamines of this type, the most frequently used procedures, e.g. via epoxides, are lengthy. An alternative approach was therefore investigated. ${ }^{2}$ The trans-adduct $\mathbf{8}^{3}$ derived from indene and $\mathrm{N}, \mathrm{N}$-dichlorourethane was selected as a precursor for both cis- and trans-1,2-diaminoindanes (Scheme 2). $\dagger$ When adduct 8 was treated with sodium azide in $N, N-$ dimethylformamide exclusive formation of the cis-azide 9 was observed. This stereochemical outcome is consistent with direct $\mathrm{S}_{\mathrm{N}} 2$ displacement, and precludes neighbouring group participation under these conditions. ${ }^{4}$

The behaviour of azide ion in this context stands in contrast to results obtained with weakly basic poor nucleophiles. For example, the reaction of adduct $\mathbf{8}$ with aniline requires assistance from the adjacent carbamate group and leads to the transsubstituted product. ${ }^{2}$ Pretreatment of the adduct 8 with sodium hydride to form the aziridine $\mathbf{1 0}$ followed by reaction with sodium azide produced the trans-isomer $11 .{ }^{5}$ The stereochemistry of the products was assigned by ${ }^{1} \mathrm{H}$ NMR

spectroscopy on the basis that the chemical shift difference between the protons at $\mathrm{C}-3$ in 1,2-disubstituted indanes is greater for trans-substitution. ${ }^{6}$ These protons appear at $\delta 2.80$ and 3.22 in cis-azide 9 whereas the trans-isomer 11 gives signals at $\delta 2.70$ and 3.30 .

Reduction of compound 9 with lithium aluminium hydride afforded the corresponding diamine 6 (Scheme 3 ). Subsequent

condensation with diethyl oxalate followed by reduction with alane produced the required cis-indenopyrazine 4 . Construction of the less favoured trans ring junction proved more difficult. Condensation of the trans-diamine 7 with diethyl oxalate failed to give the expected oxamide, presumably due to competing intermolecular reactions (Scheme 4). This problem was overcome by protection of the primary amine with a 4-methoxybenzyl group. The protected diamine precursor 13 was obtained by reaction of 8 with 4-methoxybenzylamine after in situ formation of the aziridine 10 . Subsequent reduction with lithium aluminium hydride afforded aminoindane 14.

Condensation of the aminoindane 14 with diethyl oxalate produced the required oxamide 15 , although the conditions were far more vigorous than those required to form the ciscompound. Reduction with alane, followed by deprotection

using trifluoroacetic acid-sulfuric acid-thioanisole ${ }^{7}$ completed the synthesis of the trans-indenopyrazine 5 .

Condensation of the cis- and trans-indenopyrazines 4 and 5 with 2 -chloronicotinonitrile produced 17 and $\mathbf{1 8}$ respectively (Scheme 5). Alkaline hydrolysis of compounds 17 and 18, employing milder conditions in the case of the trans-isomer 18 to avoid epimerisation, afforded the acids 19 and 20, respectively. Reduction with lithium aluminium hydride gave the alcohols 21 and 22. The trans-alcohol 22 cyclised smoothly in methanesulfonic acid-phosphorous pentoxide to give the triazabenzocycloheptafluorene 2. Under similar conditions the cis-precursor 21 was recovered unchanged. The desired cyclisation of compound 21 was effected using polyphosphoric acid at $100^{\circ} \mathrm{C}$ although the yield was modest. The isolation of indan-2-one as a minor product from this reaction suggests that the low yield of the triazabenzocycloheptafluorene $\mathbf{1}$ is due at least in part to a competing fragmentation pathway (path a in Scheme 5 followed by hydrolysis).
${ }^{1} \mathrm{H}$ NMR spectra of triazabenzocycloheptafluorenes 1 and 2 revealed couplings ( $J$ ) of 7 and 10 Hz , respectively, for the methine protons at $\mathrm{C}-12 \mathrm{c}$ and $\mathrm{C}-4 \mathrm{a}$. In the case of the cisisomer 1 confirmation of stereochemistry was provided by an X-ray analysis (Fig. 1).

## Experimental

Melting points were obtained on a Kofler hot-stage apparatus and are uncorrected. NMR spectra were recorded on a Varian CFT-20, a JEOL GX-270, a Bruker WM-250 or a Bruker AM400 spectrometer using tetramethylsilane as internal standard with coupling constants $(J)$ given in Hz . Mass spectra were obtained on an AEI MS9 ( 70 ev ) or a JEOL DX303 ( 70 ev ) spectrometer and IR spectra on a Perkin-Elmer 197 spectrometer. All evaporations of solvent were carried out under reduced pressure, and organic solutions were dried over sodium sulfate. Silica gel used for column chromatography was Merck

After stirring at room temp. for 1 h , standard work-up followed by chromatography on silica gel using $10 \%$ methanol in ethyl acetate as eluent afforded the alcohol $22(0.49 \mathrm{~g}, 73 \%)$, $v_{\max }(\mathrm{KBr}) / \mathrm{cm}^{-1} 3150(\mathrm{OH}) ; \delta_{\mathrm{H}}\left(80 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right) 2.30-3.30(10$ $\mathrm{H}, \mathrm{m}$, overlapping), $4.56(1 \mathrm{H}, \mathrm{d}, J 14, \mathrm{CHOH}), 4.65(1 \mathrm{H}, \mathrm{d}, J 9$, $4 \mathrm{a}-\mathrm{H}), 4.98(1 \mathrm{H}, \mathrm{d}, J 14, \mathrm{CHOH}), 5.90(1 \mathrm{H}, \mathrm{d}, J 8$, aromatic), $6.70-7.35(4 \mathrm{H}, \mathrm{m}$, aromatic), $7.65(1 \mathrm{H}, \mathrm{dd}, J 7$ and 2 , aromatic) and $8.65\left(1 \mathrm{H}\right.$, dd, $J 4$ and 2, aromatic) (Found: $\mathrm{M}^{+}, 295.1690$. $\mathrm{C}_{18} \mathrm{H}_{21} \mathrm{~N}_{3} \mathrm{O}$ requires $M, 295.1685$ ). To a stirred solution of alcohol $22(0.83 \mathrm{~g}, 2.8 \mathrm{mmol})$ in methanesulfonic acid ( $2.9 \mathrm{~cm}^{3}$ ) was added phosphorous pentoxide ( 2.0 g ) and the mixture was stirred at room temperature for 48 h . The reaction was poured into ice, basified with $40 \%$ sodium hydroxide and extracted into chloroform. Chromatography on silica gel using $5 \%$ methanol in ethyl acetate as eluent afforded the title compound $2(0.64 \mathrm{~g}$, $82 \%$ ), $\delta_{\mathrm{H}}\left(270 \mathrm{MHz}, \mathrm{CDCl}_{3}\right), 2.28(1 \mathrm{H}, \mathrm{m}, 4 \mathrm{a}-\mathrm{H}), 2.43(3 \mathrm{H}, \mathrm{s}$, $\mathrm{CH}_{3}$ ), 2.60-2.86 ( $2 \mathrm{H}, \mathrm{m}$, overlapping, 4-H and 6-Hax), $2.93(1$ H, dd, J 15 and 7, 4-H), 3.02 ( $1 \mathrm{H}, \mathrm{m}, 6-\mathrm{Heq}$ ), 3.38 ( $1 \mathrm{H}, \mathrm{d}, J$ $15,12-\mathrm{H}), 3.51(1 \mathrm{H}$, ddd, $J 15,13$ and $4,7-\mathrm{Hax}), 4.28(1 \mathrm{H}$, $\mathrm{d}, J 15,12-\mathrm{H}), 4.55(1 \mathrm{H}, \mathrm{br} \mathrm{d}, J 15,7-\mathrm{Heq}), 4.74(1 \mathrm{H}, \mathrm{d}, J 10$, $12 \mathrm{c}-\mathrm{H}), 6.65(1 \mathrm{H}, \mathrm{dd}, J 9$ and 5 , aromatic), $7.0-7.16(3 \mathrm{H}, \mathrm{m}$, aromatic), $7.28(1 \mathrm{H}, \mathrm{m}$, aromatic) and $8.08(1 \mathrm{H}, \mathrm{dd}, J 5$ and 2 , aromatic); $\delta_{\mathrm{C}}\left(68 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right) 32.54,37.62,43.23,47.05$, $54.82,66.42,73.02,115.69,123.37,124.73,127.94,128.80$, $135.59,136.59,137.92,139.93,145.93$ and $156.89 ; m /=277$ $\left(\mathrm{M}^{+}, 15 \%\right), 262(28), 233(16), 220(100), 219$ (40) and 204 (10) (Found: $\mathbf{M}^{+}, 277.1580 . \quad \mathrm{C}_{18} \mathrm{H}_{19} \mathrm{~N}_{3}$ requires $M$, 277.1579). Maleate salt, m.p. $206-207^{\circ} \mathrm{C}$ (decomp.) (from acetone-ether) (Found: C, 67.3; H, 5.8; N, 10.7. $\mathrm{C}_{22} \mathrm{H}_{23} \mathrm{~N}_{3} \mathrm{O}_{4}$ requires $\mathrm{C}, 67.2 ; \mathrm{H}, 5.9 ; \mathrm{N}, 10.7 \%$ ).

Crystal Data for Compound 1. $-\mathrm{C}_{18} \mathrm{H}_{19} \mathrm{~N}_{3}, M=277.37$. Orthorhombic, $a=8.644$ (1), $b=15.179$ (2), $c=22.204$ (4) $\AA$, $V=2913 \AA^{3}$, space group Pnab, $Z=8$. The compound is a racemate. $R=0.054$ for 1367 independent observed reflections [Fo $>3 \sigma(\mathrm{Fo}) ; 0 \leqslant 55^{\circ}$ with $\mathrm{Cu}-\mathrm{K} x$ radiation]. Tables of
fractional coordinates, bond lengths and angles, hydrogen coordinates and thermal parameters have been deposited with the Cambridge Crystallographic Database.*
