Imines derived from 1,2,3-thiadiazole-4-carbaldehyde 4 rearrange thermally into 1,2,3-triazole-4thiocarbaldehydes 6 which were trapped with anthracene or 2,3-dimethylbutadiene. In two cases, 1,2,3-thiadiazole-4-thiocarbaldehyde 9 was intercepted as the Diels-Alder adduct 11. 5-Phenyl-1,2,3-thiadiazole-4-carbaldehyde 14 reacts with amines to give 4-benzoyl-1,2,3-triazoles 17 via the intermediate 4-thiobenzoyltriazoles 16, whose existence has been demonstrated by NMR. The reactions of 5-tert-butylthio-1,2,3-thiadiazole-4-carbaldehyde 18 with amines yield either 1,2,3-triazole-4-dithio esters 20 or 1,2,3-triazole-4-thioamides 21 . In solution, the dithioesters 20 equilibrate with the imines 19 when the $R$-substituent is aryl. From the reaction conditions we conclude that the facility of rearrangement of the title compounds depends on the nucleophilicity of the imine nitrogen and on the 5 -substituent in the order $\mathrm{Bu}^{t} \mathrm{~S}>\mathrm{Ph}>\mathrm{H}$.

Recently we reported that 5-chloro-1,2,3-thiadiazole-4-carbaldehyde 1 reacts with amines to give 1,2,3-triazole-4-thiocarboxamides 2 via $x$-diazo thioketone intermediates. ${ }^{1}$ This reaction is similar to the Cornforth rearrangement of 4 -carbonyl substituted oxazoles, ${ }^{2}$ and to the ring-degenerate rearrangement of 4-iminomethyl substituted $1 \mathrm{H}-1,2,3$-triazoles ${ }^{3}$ which all involve the participation of two side-chain atoms during the rearrangement. In contrast, the classical Dimroth rearrangement of 5-amino substituted thiadiazoles and triazoles involve the exchange of the exocyclic N -atom with the adjacent endocyclic S - or N -atom. ${ }^{4}$ In continuation of our research in this field, we have now investigated the generality of the title thiadiazole-triazole rearrangement by introducing different substituents at the 5-position; i.e. H, Ph and SR. The results are discussed below.

The parent aldehyde 4 was prepared from methylglyoxal 3 by the method of Kobori et al. ${ }^{5}$ and treated with a series of amines in ethanol at room temperature. The products $5 \mathbf{a}-\mathrm{h}$ all had the $E$-configuration about the $\mathrm{C}=\mathrm{N}$ bond as evidenced by the onebond ${ }^{13} \mathrm{CH}=\mathrm{N}$ coupling constants of $164-167 \mathrm{~Hz}$ which would be larger for the $Z$-isomers (ca. 177 Hz ). ${ }^{6}$ This cis-relationship between the thiadiazole ring and the imine-nitrogen lone pair is a necessary condition for observing any rearrangement to a triazole. ${ }^{7}$ This was found to be the case for the imines $5 a-f$ which rearranged readily in tetrahydrofuran or toluene at $65^{\circ} \mathrm{C}$, and for 5 g which required heating in toluene at $110^{\circ} \mathrm{C}$. In contrast, the imine $\mathbf{5 h}$ remained unchanged in dimethyl sulfoxide at $120^{\circ} \mathrm{C}$ although it also possessed the $E$ configuration ( ${ }^{1} J 164$ ). The thermolyses were carried out in the presence of anthracene or 2,3-dimethylbutadiene as traps ${ }^{8}$ for the thioaldehydes 6, resulting in the formation of the DielsAlder adducts 7a, b,g and 8c-f (Scheme 1).

The imines 5a, b furnished the expected products 7a, b with anthracene, but with 2,3-dimethylbutadiene the same thiadiazole derivative 11 was isolated in both cases together with the triazoles 12a, b. This is rationalized in Scheme 2 where the intermediate thioaldehydes $\mathbf{6 a}$, b undergo $\mathbf{a}(2+2)$ -cycloaddition-cycloreversion process with unchanged $\mathbf{5 a}, \mathbf{b}$ to

give the thioaldehyde 9 and the iminotriazoles $10 a, b$. Compound 9 is trapped with the diene under the reaction conditions to give the thiadiazole derivative 11 , whereas the imines $10 \mathrm{a}, \mathrm{b}$ are hydrolysed during the chromatographic workup procedure.

Differentiation between the triazoles and the thiadiazoles is easily made on the basis of their ${ }^{13} \mathrm{C}$ NMR spectra. Indeed, the triazoles 7, 8 and 12 exhibit characteristic C-4 and C-5 resonances at $\delta 148-150$ and $\delta 118-124$ respectively, whereas those of the thiadiazole 11 occur at lower field (C-4 at $\delta$ 164.7, C-5 at $\delta 132.1$ ), and in the same region as those of the aldehyde 4 (C-4 at $\delta 161.9, \mathrm{C}-5$ at $\delta 140.7$ ) and the imines 5 (C-4 at $\delta 161-$

Scheme 2
162, C-5 at $\delta$ 134-137). The incremental substituent effects for triazoles and thiadiazoles have been discussed recently. ${ }^{9}$
We next investigated the influence of a 5 -phenyl substituent on the ease of rearrangement of thiadiazoles. 5-Phenyl-1,2,3-thiadiazole-4-carbaldehyde 14 was readily obtained from the known 5-phenylthiadiazole 13 by treatment of its 4 -lithio derivative ${ }^{10}$ with $N$-formylmorpholine in tetrahydrofuran at $-70^{\circ} \mathrm{C}$ (Scheme 3). This method has already been utilized successfully by Olah ${ }^{11}$ and Dondoni ${ }^{12}$ to prepare different aldehydes.

Methylamine and ethylamine reacted with compound 14 at room temperature to give products which were characterized as the 4 -benzoyltriazoles $17 \mathbf{a}, \mathbf{b}$ on the basis of their spectral data. Under similar conditions, isopropylamine, tertbutylamine, aniline and $p$-methoxyaniline provided a mixture

of the imines $\mathbf{1 5 c}-$ f and ketones $\mathbf{1 7 c} \mathbf{c}$-f, and complete conversion into $\mathbf{1 7 c} \mathbf{c}$ f was achieved in refluxing ethanol. The imine $\mathbf{1 5 g}$, derived from $p$-chloroaniline, did not rearrange at room temperature but gave the ketone 17 g at $120^{\circ} \mathrm{C}$ in dimethyl sulfoxide solution. In contrast, 3,4-dichloroaniline yielded the imine 15 h which proved to be stable at $100-120^{\circ} \mathrm{C}$. From these results we conclude that the propensity of the imines 15 to rearrange depends on the nucleophilicity of the imine nitrogen.

That the rearranged products have structure 17 instead of 16 is evident from the $\mathrm{C}=0$ stretching absorptions at $\sim 1650 \mathrm{~cm}^{-1}$ in their IR spectra and the typical ketone C signals at $\delta \sim 185$ in their ${ }^{13} \mathrm{C}$ NMR spectra; aromatic thioketones would resonate at $\delta 210-240 .{ }^{13}$ In order to elucidate the mechanism of the conversion $16 \rightarrow 17$, we have followed the reaction of isopropylamine with a slight excess of the aldehyde 14 in deuteriated chloroform by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopy. The imine 15c was formed first at room temperature, and the thioketone 16 c was obtained after 2 h at $60^{\circ} \mathrm{C}\left(\mathrm{C}=\mathrm{S}\right.$ at $\left.\delta_{\mathrm{c}} 222\right)$. The blue colour of 16 c remained unchanged when the solution was stored at room temperature, even in the presence of $\mathrm{D}_{2} \mathrm{O}$, but disappeared immediately upon addition of isopropylamine. The NMR spectrum then showed resonances of the ketone 17 c . This experiment indicates that hydrolysis of the thioketones 16 is catalysed by the amine present in excess. Full details of the NMR data are given in the Experimental section, but it is appropriate to note here that the phenyl C-ipso resonates at much lower field in the thioketone $16 \mathrm{c}(\delta 145.5)$ than in the ketone $17 \mathrm{c}(\delta 136.7)$ as expected. ${ }^{14}$
Since the chloro aldehyde 1 is readily substituted by alkanethiolates, we have also prepared the tert-butyl derivative 18 and studied its reactions with amines. Methylamine, ethylamine and isopropylamine yielded the triazole-4-thiocarboxamides 21a-c, apparently as a result of rearrangement of the imines 19a-c, followed by nucleophilic substitution of the dithioester function of 20a-c by amine (Scheme 4). The amount of amine used (1 or more equivalents) had no influence on the

outcome of the reactions, indicating that aminolysis of the dithioesters 20 is a fast process. The products 21a, $\mathbf{b}$ have already been obtained from compound 1 and amines, ${ }^{1}$ and were further characterized by the triazole resonances ${ }^{9}$ at $\delta 148(\mathrm{C}-4)$ and $\delta 125-129(\mathrm{C}-5)$, and the thioamide resonances ${ }^{15}$ at $\delta 184$ in the ${ }^{13} \mathrm{C}$ NMR spectra.
tert-Butylamine and aromatic amines also reacted with the aldehyde 18 at room temperature, but furnished rose-red coloured products which were identified as the dithioesters $\mathbf{2 0 d}-$ h. These compounds exhibited $\mathrm{C}=\mathrm{S}$ carbon resonances at $\delta 214$ 215 in their NMR spectra. ${ }^{16}$ Furthermore, when freshly prepared chloroform solutions of the aromatic derivatives $\mathbf{2 0 e}$ $h$ were analysed, the NMR spectra indicated the presence of minor amounts of the imines $19 e-h$, whose concentrations increased with time until equilibria positions were reached. The results are summarized in Table 1 and point out that the shift towards the imine is favoured by electron-withdrawing $R$ substituents. This is most pronounced for the dichlorophenyl derivative 20 h which equilibrates with $50 \%$ imine $\mathbf{1 9 h}$ after 1 day in deuteriated chloroform treated with alumina. The same equilibrium position was reached in untreated chloroform, but only after several days. In other solvents, such as deuteriated benzene, tetrahydrofuran and acetonitrile, the equilibrium concentration of 19 h is much lower, 30,20 and $27 \%$ respectively; hence, no correlation with the solvent polarity was found.
