The cycloadditions of a series of 4 H -pyran-4-ones 3c-e with electron-rich dienes 11a,b to give reduced flavones 12 is described. The subsequent reactions of these reduced flavones with HCI , trifluoroacetic anhydride, ethyl anthranilate 19a and anthranilonitrile 19b is also described.

We have recently described the synthesis of a series of pyranoacridinones, e.g. $\mathbf{1},{ }^{1}$ which are potent inhibitors of the

spontaneous proliferation of a human-derived gastric carcinoma cell line, MKN 45, but are non-cytotoxic. ${ }^{2}$ A key intermediate in the synthesis of these pyranoacridinones is 7 -oxo-5,6,7,8-tetrahydroflavone 2 and, as part of our ongoing investigation into the biological potential of these pyranoacridinones, we have become interested in an alternative, more efficient, synthesis of reduced flavones. We have previously reported a novel method for the synthesis of reduced flavones based on the Diels-Alder reactions of 4 H -pyran-4-ones with electron-rich dienes. ${ }^{3}$ To date very little attention has been paid to cycloadditions of 4 H -pyran-4-ones, in contrast to the welldocumented reactivity of 4 H -benzopyran- 4 -ones ${ }^{4-8}$ or benzothiopyranones. ${ }^{9}$ The only example of the cycloaddition of 4 H -pyran-4-ones is a footnote by M CCombie et al. ${ }^{10}$ in their paper on the preparation of these compounds in which pyranone 3c readily reacted with diazomethane in a 1,3-dipolar cycloaddition to give the adduct 4. In this paper we describe our experimental procedures for the preparation of these ring systems, together with some observations on their chemical reactivity.

## Results and discussion

## Synthesis of 4H-pyran-4-ones

Initially, we required a standard synthesis of a range of substituted pyranone dienophiles for the Diels-A Ider reaction. A fter reviewing the literature the following methodologies were used, mostly with slight modifications. We have prepared the 2-phenyl-4H -pyran-4-one 3a by a modification of Reynolds' method (Scheme 1). ${ }^{11}$ The main differences in our procedure are

Scheme 1 Reagents and conditions: $\mathrm{i}, \mathrm{Ac}_{2} \mathrm{O}, \mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}$; ii, $\left(\mathrm{CH}_{3}\right)_{2^{-}}$ $\mathrm{NCH}\left(\mathrm{OCH}_{3}\right)_{2}, \mathrm{DMF}$; iii, $\mathrm{HClO}_{4}, \mathrm{EtOH}$
the use of boron trifluoride-diethyl ether rather than gaseous boron trifluoride, and the work-up procedure in the final step (three steps, $21 \%$ overall yield). The method used first by Borsche and Peter ${ }^{12}$ proved to be an easy route to ethyl 4-oxo-6-phenyl-4H -pyran-2-carboxylate 3b, in good yield (Scheme 2).

Scheme 2 Reagents and conditions: $\mathrm{i}, \mathrm{Br}_{2}$; $\mathrm{ii}, \mathrm{AcOK}$, dry EtOH
The preparation of 6-aryl-4-oxo-4H-pyran-3-carboxylates 3c-e has been described by McCombie et al. (Scheme 3). ${ }^{10}$ This procedure is based on simple starting materials with two effective steps for the formation of the pyranone ring. We have altered

Scheme 3 Reagents and conditions: i, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NCH}\left(\mathrm{OCH}_{3}\right)_{2}, 80^{\circ} \mathrm{C}$; ii $\mathrm{ArCOCl}, \mathrm{LiN}\left(\mathrm{SiM} \mathrm{e}_{3}\right)_{2},-70^{\circ} \mathrm{C}$; iii, $\mathrm{HCl}, \mathrm{H}_{2} \mathrm{O}$, room temp.
the method for the synthesis of the intermediate enaminone 10; instead of using a dimethylformamide (D M F)-dimethyl sulfate adduct, the enaminone $\mathbf{1 0}$ was formed by simple heating of the corresponding keto ester 9 with dimethylformamide dimethyl acetal without the presence of any solvent. ${ }^{13}$ With this modification we have prepared the pyranones $\mathbf{3 c}$ - 3 e in $40-60 \%$ yield.

## D iels- A Ider reactions

The pyranone 3a without any additional electron-withdrawing groups, and the pyranone 3b, were unreactive towards 2 trimethylsilyloxybuta-1,3-diene 11a and Danishefsky's diene 11 b under normal or forced (neat, $160^{\circ} \mathrm{C}$ or Lewis-acid catalyst) conditions, while pyranones 3 c - 3e reacted smoothly with 11 b and the reaction resulted in formation of the cycloadducts 12a-c in good yield (Scheme 4). The addition of 3c to 2

trimethylsilyloxybuta-1,3-diene 11a under the same conditions proceeded more slowly, due to the lower reactivity of the diene, and gave the cycloadduct 12d in poor yield (12d could not be isolated; the ketone 16c was isolated in $16 \%$ overall yield, after treatment of 12d with 0.01 m aqueous $\mathrm{HCl}-\mathrm{THF}$, followed by chromatography).

The ${ }^{1} H$ NMR spectra of the cycloadducts indicate the presence of only one diastereoisomer, which is quite remarkable as the analogous process led to a 1:1 mixture of diastereoisomers in the benzopyranone series. ${ }^{4}$

We have attempted to determine the relative stereochemistry of cycloadduct 12a by ${ }^{1} \mathrm{H}\left\{{ }^{1} \mathrm{H}\right\}$ N OE difference spectroscopy, but irradiation of the doublet for $\mathrm{H}-5(\delta 4.56)$ gave only a large NOE to H-6 and a medium NOE to the OM e. Irradiation of the OM e ( $\delta 3.23$ ) was inconclusive. The 3D structure of the cycloadduct 12a was therefore determined by X-ray crystallography and shows that the methoxy group at C-5 and the ester group at C-4a are trans to one another, with the methoxy group in a pseudo-axial position (Fig. 1).

Similar observations were made when the ester-stabilised azomethine ylide 14 (generated from imine 13 in the presence of LiBr as a catalyst) acted as a $4 \pi$ component in a 1,3-dipolar cycloaddition; ${ }^{14}$ whilst $\mathbf{3 a , b}$ were unreactive, in the reaction with pyranone 3d the cycloadduct 15 was formed in good yield (Scheme 5). The configuration of cycloadduct $\mathbf{1 5}$ depicted was verified by ${ }^{1} \mathrm{H}\left\{{ }^{1} \mathrm{H}\right\}$ NOE difference spectroscopy, the irradiation of H-7 ( $\delta 5.14$ ) caused enhancement of $\mathrm{H}-7 \mathrm{a}(5 \%)$, and

of the ortho protons of the 7-phenyl group (7\%) whilst there was no N OE observed between $\mathrm{H}-7$ and $\mathrm{H}-5$.

## D eprotection of Diels-Alder adducts

Treatment of the cycloadducts $\mathbf{1 2 a}, \mathbf{b}$ with 0.01 m HCl in THF gave the corresponding desilylated products 16a,b. The brief treatment of 12 or $\mathbf{1 6}$ with trifluoroacetic anhydride (TFAA) gave the enones 17a,b (Scheme 6). In both the treatment with hydrochloric acid and the TFAA, epimerisation of $\mathrm{H}-8 \mathrm{a}$ was observed to give a $1: 1$ mixture of diastereoisomers. This is unimportant in the synthesis of the pyranoacridinones, e.g. 1, since the groups at the 4a- and 8a-positions will be lost upon aromatisation.

## Reduction of enone 17a

To achieve the synthesis of 7-oxotetrahydroflavone $\mathbf{2}$ or an analogue the selective reduction of the 5,6 -double bond of 17 a was necessary (the direct synthesis of $\mathbf{1 6 c}$ proceeded in poor yield). Our attempts to reduce 17a by means of $\mathrm{PtO}_{2}-\mathrm{H}_{2}$, tris(triphenylphosphine)chlororhodium(r) (ethanol, $60^{\circ} \mathrm{C}$, $40 \mathrm{psi} \ddagger$ ), ${ }^{15}$ or Red-AI-CuBr ${ }^{16}$ were unsuccessful. In all cases only the starting material was recovered. The reduction of 17a with Red-AI gave a complex mixture of products. The use of a large excess of $\mathrm{NaBH}_{4}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution resulted in the reduction of the 7oxo group quantitatively and selectively, giving a mixture of diastereoisomers 18 (Scheme 7).

## Reaction of reduced flavones with anthranilic acid derivatives

The condensation of $\mathbf{1 2 a}$ or $\mathbf{1 2 b}$ with the primary aromatic amines under the standard conditions for azeotropic removal

of water, in the presence of a catalytic amount of toluene-psulfonic acid (PTSA ), resulted in an interesting degradation of the flavone ring system ( $\mathbf{1 2}$ was deprotected immediately under the harsh conditions used) (Scheme 8). F rom the complex mix-

ture of products obtained from the reaction of 12a or 12b with ethyl anthranilate 19a, three were identified and at least two by-products remained unidentified (shown by TLC). The main
product 20a crystallised out from the reaction mixture after cooling in both cases. Compounds 21 (identified by comparison of spectroscopic data with literature values ${ }^{17}$ ) and 22a, 22b and 22c were separated by column chromatography as minor products. The same reactivity was observed in the reaction of anthranilonitrile 19b with 12a. These results suggest that the reaction with the amine is not regioselective, i.e. unlike our earlier work with $\mathbf{2}^{1}$ there is no distinction between the two carbonyl groups.

$M$ ps were determined on a Kofler hot-stage and are uncorrected. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were acquired on a Bruker WM 360 spectrometer at 360 and 90 MHz respectively. ${ }^{1} \mathrm{H}$ NMR coupling constants (J) are given in Hz and chemical shifts ( $\delta$ ) are relative to an internal standard of tetramethylsilane. Low resolution electron impact mass spectra were obtained on a Varian CH 5-D spectrometer. Elemental analyses were performed on a Perkin-Elmer 240B. IR spectra were recorded on a Perkin-Elmer 1600 series FT-IR spectrometer using sodium chloride plates. Thin layer chromatography was performed on M erck silica gel $60 \mathrm{~F}_{254}$ and dry column flash chromatography on M erck silica gel 60 H . Tetrahydrofuran was dried from sodium-benzophenone.

## Structural analysis and refinement

The structure was solved via direct methods (SHELX-S) ${ }^{19}$ and refined on $\mathrm{F}_{0}{ }^{2}$ by full-matrix least-squares (SHELXL-93) ${ }^{20}$ using all unique data corrected for Lorentz and polarisation factors to final wR (on $F_{0}{ }^{2}$ ) and $R$ (on F) values of 0.1015 and 0.0692 for 287 parameters (non-hydrogen atoms anisotropic; hydrogens in idealised positions with $\mathrm{U}_{\text {iso }}$ stied to the $\mathrm{U}_{\text {eq }} \mathrm{S}$ of the parents). The corresponding R values for data with $I>2 \sigma(I)$ are 0.0973 and 0.0433 , respectively. The weighting scheme used was $\mathrm{w}=1 /\left[\sigma^{2}\left(\mathrm{~F}_{\mathrm{o}}{ }^{2}\right)+(0.0467 \mathrm{P})^{2}\right]$, where $\mathrm{P}=\left[\max \left(\mathrm{F}_{\mathrm{o}}\right)^{2}+2\left(\mathrm{~F}_{\mathrm{c}}\right)^{2}\right] / 3$; this gave satisfactory agreement analyses.
