#### Abstract

M ethodology has been established for the formation of enantiomerically enriched $\alpha$-amino acids using palladium-catalysed allylic amination. The formation of enantiomerically enriched allylamines has been achieved with high enantioselectivity. Oxidative cleavage of the allylamines provides arylglycine and glutamic acid derivatives. A dditionally, enantiomerically enriched $\beta$-amino acids have been prepared in high enantiomeric excess. Palladium-catalysed asymmetric allylic substitution is used as the key synthetic transformation.

Palladium-catalysed allylic substitution has found numerous applications in the synthesis of compounds with important biological activity. ${ }^{1}$ However, there have been relatively few reported syntheses of enantiomerically enriched amino acids by the use of this reaction. ${ }^{2-4}$

Herein, we report the use of palladium-catalysed allylic substitution in the preparation of enantiomerically enriched protected and deprotected $\alpha$ - and $\beta$-amino acids.

For the synthesis of $\alpha$-amino acids, the methodology comprises of two principal synthetic steps. Firstly, the reaction of an allyl acetate $\mathbf{1}$ with a nitrogen nucleophile to afford an allylamine derivative $\mathbf{2}$, followed by oxidative cleavage of the alkene to give an N -protected amino acid or ester 3 (Scheme 1).

Our initial interests lay in the construction of a general methodology to provide a useful approach to the synthesis of achiral and enantiomerically enriched $a$-amino acids. Azide, ${ }^{5}$ sulfonamide, ${ }^{6}$ phthalimide ${ }^{7}$ and di-tert-butyl iminodicarbonate ${ }^{8}$ have all been reported to be effective nitrogen nucleophiles in palladium-catalysed allylic substitutions and were also successful in our hands. This allows a wide scope in the choice of nitrogen nucleophile and the resulting $N$-protected amine. ${ }^{9}$ The reaction of the allyl acetates 4-7 with various nitrogen nucleophiles in the presence of catalytic amounts of palladium and an achiral phosphine afforded the corresponding allylamine derivatives 8-11 (Scheme 2).
With the formation of allylamines in hand, we required oxidative methods for the cleavage of alkenes into carboxylic acids and esters. The oxidative cleavage of alkenes by ozonolysis in the presence of methanolic sodium hydroxide ( 2.5 m ) at $-78^{\circ} \mathrm{C}$ has been reported by M arshall and co-workers, in which the cleavage of enantiomerically enriched allylic ethers and amines yielded the corresponding methyl esters without loss of stereochemical purity. ${ }^{10} \mathrm{U}$ sing this procedure we were able to convert allylic amine derivatives into the corresponding N -protected amino esters 14-20 (Table 1). H owever, allyl azides 10d and 11d were found to decompose under these reaction conditions. In

an additional step the azide groups were converted into the corresponding amides $\mathbf{1 2}$ and $\mathbf{1 3}$ in modest yield by using thioacetic acid prior to the oxidative cleavage (Scheme 3). ${ }^{11}$
The resultant allyl amides $\mathbf{1 2}$ and $\mathbf{1 3}$ weresmoothly converted into the corresponding amino acid derivatives 18 and 20 by ozonolysis in basic methanol. The results of the oxidative cleavage by this method are listed in Table $1 .{ }^{12}$ CAUTION: On one

occasion, we experienced a small explosion whilst conducting the ozonolysis, and we therefore recommend the use of a blast shield for this procedure.
Additionally, alkenes may be oxidatively cleaved using periodate in the presence of a ruthenium catalyst. ${ }^{13}$ Thus, the allylphthalimide 8 was subjected to oxidation with catalytic $\mathrm{RuCl}_{3}$ and stoichiometric $\mathrm{NaIO}_{4}$ and afforded the expected product $21(47 \%)$ (Scheme 4). Higher yields were obtained with substituted allylphthalimides (vide infra).

H aving established the synthetic methodology for the formation of achiral N -protected amino esters, we wished to investigate the formation of enantiomerically enriched amino acids. In the first step, the formation of enantiomerically enriched allylamines was achieved by palladium-catalysed allylic amination with a protected nitrogen nucleophile in the presence of the enantiomerically pure phosphine oxazoline ligand 22. Ligand 22 has previously been found by this group and by others to induce very high enantioselectivity in palladium-catalysed allylations with carbon nucleophiles. ${ }^{14,15}$ We therefore chose to use this ligand with a variety of nitrogen nucleophiles, and these results are summarised in Table 2. THF appears to be the most appropriate solvent for good yields and high enantiomeric excess of allylamines. DMF and the mixtures of THF and DMSO ( $80: 20$ ) both led to diminished enantioselectivity.

Furthermore, it can be seen that not all of the nitrogen nucleophiles used achieved high enantioselectivity in the amination. The sodium salt of di-tert-butyl iminodicarbonate yielded the amination product 11c with only 54\% ee (Scheme 5) in comparison to the high enantiomeric excess achieved using potassium phthalimide or sodium toluene-p-sulfonamide when the respective reactions were carried out in TH F.

During the course of this investigation, von M att et al. and Jumnah et al. also reported palladium-catalysed enantioselective allylic amination using ligand 22. ${ }^{16,17}$

the products formed and the nitrogen nucleophiles used in a solvent mixture of THF-DM SO (80:20). It is clear that the allyl system with a phenyl terminus gives superior results, and this would appear to be a limitation of this chemistry. However, the use of substrates which do not proceed through symmetrical allyl systems allows this problem to be overcome with some nucleophiles (vide infra).
In order to prepare enantiomerically pure amino acid derivatives, an oxidative cleavage of the alkene moiety was required. Treatment of compound 11a with periodic acid in the presence of a ruthenium catalyst effected oxidative cleavage to give the carboxylic acid. ${ }^{13}$ The carboxylic acid could only be purified by crystallisation, and since this could enhance the enantiomeric excess of the product, we converted it directly into
the methyl ester to give the protected phenylglycine derivative 24 (this compound was readily purified by column chromatography) (Scheme 6). Alternatively, deprotection of the phthalimide group in the presence of sodium borohydride yielded the free amino acid 25 from allylamine $23 .{ }^{18}$ In both arylglycine products $\mathbf{2 4}$ and $\mathbf{2 5}$, there was no observed erosion of stereochemical purity. A mino acid 25 was confirmed to be

In a differing synthetic strategy, a d-glutamic acid derivative was prepared. The alkene 11a was reduced by heterogeneous hydrogenation in the presence of a palladium catalyst to give the corresponding alkane 26. The benzylic phthalimide group proved to be inert to the hydrogenation conditions employed. Oxidative cleavage of the phenyl groups was carried out in the presence of periodic acid and a ruthenium catalyst to yield the dicarboxylic acid, ${ }^{20}$ which was further transformed to the diester $\mathbf{2 7}$ with preservation of stereochemical purity (Scheme 7). It was found that the selective oxidative cleavage of the phenyl rings could be achieved without the cleavage of the phthalimide group. This is consistent with the fact that electron-deficient aryl groups are less susceptible to oxidative cleavage under these conditions, ${ }^{20}$ although elevation of the temperature to over $50^{\circ} \mathrm{C}$ led to degradation of the product.

Several research groups have shown that unsymmetrical allylic acetates such as compounds 28a-d undergo palladiumcatalysed enantioselective allylic substitutions. ${ }^{21}$ We have recently successfully applied the ligand 22 to this reaction, ${ }^{22}$ which provides a convenient access to the products 29a-d in high yield and excellent enantioselectivity (Scheme 8). H owever, we were unable to obtain a reaction between allylic acetate 28a or 28b and a nitrogen nucleophile using a palladium-catalysed reaction. This is unfortunate, since substrates of this type are easily prepared from $\beta$-phenylcinnamaldehyde ${ }^{22}$ and would have allowed a greater range of $a$-amino acids to be prepared.

N evertheless, we felt that the use of substrates 28a-d (and related structures) may offer some potential for the synthesis of $\beta$-amino acids. Indeed, this has proved to be successful and the results are described below.
The enantiomerically pure products 29a-d were decarboxylated using the K rapcho procedure ${ }^{23}$ affording the mono-esters 30a-d (Scheme 9). Hydrolysis of the decarboxylated products 30a-d afforded the mono-acid compounds 31a-d in high yield. These carboxylic acids were subjected to a modified Curtius reaction. ${ }^{24}$ Thus, treatment of mono-acids 31a-d with diphenylphosphoryl azide and triethylamine in refluxing tert-butyl alcohol afforded the tert-butoxycarbonylamino products 32a-d in reasonable yield. Oxidation of compounds 32a-d with sodium metaperiodate and a ruthenium catalyst ${ }^{13}$ afforded the corresponding protected $\beta$-amino acids 33a-d in reasonable yield. In order to demonstrate that this methodology can be used to access free $\beta$-amino acids, the substrates 33a and 33b were converted into the free $\beta$-amino acids 34a and 34b by acid hydrolysis in good yield. There was no loss of stereochemical purity in the synthesis of compound 34a indicating that this methodology does not lead to significant racemisation.

Chiral $\beta$-amino acids can have their asymmetric centre either $\alpha$ or $\beta$ to the carbonyl group. In the examples above, the asymmetric centre is generated in the $\alpha$-position. H owever, by modification of the reaction sequence, $\beta$-amino acids may be prepared in which the asymmetric centre is in the $\beta$-position. Thus, the mono-ester 30c was subjected to catalytic rutheniumsodium metaperiodate oxidising conditions, producing the product 35 in reasonable yield (Scheme 10). Treatment of 35 under modified Curtius reaction conditions afforded the tertbutoxycarbonylamino compound 36 in reasonable yield (which proceeds with retention of configuration). F inally, hydrolysis of the mono-ester 36 afforded the desired product 37 in good yield and with excellent enantioselectivity, as determined by chiral H PLC [Chiralcel OD, hexane-isopropyl alcohol ( $80: 20$ )].

In summary, we have described an effective and highly enantioselective synthesis of $\alpha$ - and $\beta$-amino acids. Palladiumcatalysed asymmetric allylic substitution was the key step in the preparation of both classes of compound.

## Experimental

Commercially available solvents and reagents were used throughout without further purification, except for those detailed below which were purified as described. Light petroleum refers to the fraction boiling in the range $40-60^{\circ} \mathrm{C}$, and was distilled through a 36 cm Vigreux column before use. Diethyl ether (referred to as ether) was dried by storage over sodium wire for several days. THF was distilled from sodium benzophenone ketyl under nitrogen, prior to use. Dichloromethane was distilled from phosphorus pentoxide. In order to dry DM F, it was stirred over calcium hydride for 15 h , decanted and distilled under reduced pressure before storage over $4 \AA$ molecular sieves under nitrogen.

A nalytical thin layer chromatography was carried out using aluminium-backed plates coated with M erck K ieselgel 60 $\mathrm{GF}_{\text {254. }}$. Plates were visualised under UV light (at 254 and/or 360 nm ) or by staining with phosphomolybdic acid reagent, followed by heating. F lash chromatography was carried out using M erck K ieselgel 60 H silica or Sorbsil C 60 silica gel. Pressure was applied at the column head with hand bellows. Samples were applied pre-adsorbed on silica or as a saturated solution in an appropriate solvent.

IR Spectra were recorded in the range $4000-600 \mathrm{~cm}^{-1}$ using a N icolet FT-205 spectrometer, with internal calibration. Spectra were recorded as solutions in chloroform. Elemental analyses were carried out on a Perkin-Elmer 2400 Elemental A nalyser. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ N M R spectra were recorded using Bruker AC-250 and Bruker WH-400 (SERC N M R Spectroscopy Centre, Warwick) instruments. High- and low-resolution mass spectra were recorded on a K ratos M S80 instrument or on a VG A nalytical ZAB-E instrument (EPSRC mass spectrometry service, Swan-
sea). Optical rotations were carried out on an Optical A ctivity AA 100 polarimeter and are recorded as $10^{-1}$ degrees $\mathrm{cm}^{2} \mathrm{~g}^{-1}$. M ps were measured on an Electrothermal digital melting point apparatus and are uncorrected. The preparations of ligand 22, allyl acetates 4-7 and 28a-d and the substitution products 29a-d have been detailed elsewhere. ${ }^{16,22}$
