#### Abstract

G lucosamine donors 1-3 having N-TCP, N,N-diacetyl and N-Teoc protection, respectively, give with $\mathbf{N}^{\alpha}$-B oc-protected serine and threonine benzyl esters 4a,b as acceptors exclusively the $\beta$-glycosides; they can be transformed into 0-G IcN A c serine and threonine derivatives 8a,b. The high yielding 0 -glycosylation of compounds $4 a, b$ with trichloroacetimidate 3 and the ease of replacement of the N -Teoc group by the N -acetyl group prompted the use of $\mathbf{N}^{\text {a }}-\mathrm{F}$ moc-protected serine and threonine allyl ( $9 \mathrm{a}, \mathrm{b}$ ) and Pfp active esters (12a,b) as acceptors, thus very efficiently yielding the corresponding 0-( $\mathrm{N}, 0-$ acetylglucosamino) serine and threonine derivatives $11 \mathrm{a}, \mathrm{b}$ and $14 \mathrm{a}, \mathrm{b}$ as active esters.

## Introduction

Intracellular posttranslational protein glycosylation, through which $N$-acetylglucosamine ( GIcNAc ) residues are $\beta$-glycosidically linked to the hydroxy group of serine and/or threonine, has been observed for some time. ${ }^{1}$ R ecently, it has been shown that the $\beta$-amyloid precursor protein (APP), which is associated with A Izheimer's disease, is also posttranslationally modified by $0-\mathrm{GIcNAc}$ residues. ${ }^{2}$ The specific functions of $0-\mathrm{GIcNAc}$ attachment to proteins have not yet been fully elucidated. Indirect evidence led to the hypothesis that the 0-G IcN A c linkage may often have a reciprocal relationship to the regulatory effect of protein phosphorylation. ${ }^{3}$ Therefore, access to glycopeptides carrying $\beta$-linked $0-\mathrm{GIcNA}$ c residues became of great interest. ${ }^{4-6}$

Still the most efficient approach to glycopeptide synthesis is based on O -acyl-protected O - or N -glycosyl amino acid active esters, for instance $\mathrm{N}^{\text {a }}$-fluorenylmethoxycarbonyl amino acid pentafluorophenyl esters ( $\mathrm{N}^{\mathrm{a}}$ - $\mathrm{Fmoc-AA-OPfp)}$, ${ }^{7-10}$ which are used as building blocks for the stepwise construction of glycopeptides at a solid phase. Therefore, efficient access to Nprotected serine and threonine active esters already possessing O-linked GIcNAc residues, as described in this report, eases glycopeptide synthesis. Based on the $N$-allyloxycarbonyl (Aloc) group and the N -dithiasuccinoyl (Dts) group a similar approach has been recently reported. ${ }^{4,5}$ H owever, not only the ease of formation of the glycosyl donor but also the stability of the N -protecting group, required for activation in the glycosylation step, and a direct and high yielding transformation of 0 -glycosyl amino acid active esters into the corresponding $0-\mathrm{GlCNAc}$-containing compounds are important aspects in this endeavour. M ethods for the synthesis of glucosaminecontaining serine and threonine derivatives, in which the N -acetyl group is generated only after glycopeptide synthesis, have also been reported. ${ }^{5,8,11,12}$

## Results and discussion

Glucosamine can be readily transformed into glycosyl donors 1-3, ${ }^{13-15}$ they exhibit high glycosyl-donor properties because formation of stable oxazolinium intermediates is prevented by the presence of strongly electron-withdrawing groups; yet high $\beta$-selectivity can still be expected through neighbouring-group participation. Thus, reaction of N -tetrachlorophthaloyl (TCP)protected glycosyl donor $\mathbf{1}^{13}$ with N -tert-butoxycarbonyl (BOC)-

protected serine and threonine benzyl esters $\mathbf{4 a}, \mathbf{b}^{16}$ furnished, in the presence of catalytic amounts of trimethylsilyl trifluoromethanesulfonate (TM SOTf, 0.01 mol equiv.), as expected the $\beta$-anomers $5 \mathbf{a}$,b in $75 \%$ yield ( $1-\mathrm{H}: \mathbf{5 a}: \delta_{\mathrm{H}} 5.34, \mathrm{~J}_{1,2} 8.4 \mathrm{~Hz} ; \mathbf{5 b}$ : $\delta_{\mathrm{H}}$ $5.3, J_{1,2} 8.3$ ). H owever, the removal of the $N-T C P$ group with ethylenediamine at $60^{\circ} \mathrm{C}^{17}$ and then per-acetylation with acetic anhydride in pyridine, to afford target molecules 8a,b, was not satisfactory; various by-products were formed (Scheme 1).

The $\mathrm{N}, \mathrm{N}$-diacetyl thioglycoside $\mathbf{2}^{14}$ was activated by N -iodosuccinimide ( $\mathrm{NIS}, 1.5 \mathrm{~mol}$ equiv.) and TfOH ( 0.01 mol equiv.), giving, by reaction with acceptors $4 \mathbf{a}, \mathbf{b}$, the desired $\beta$-glycosides $6 \mathbf{a}, \mathbf{b}$ in only $50 \%$ yield (1-H:6a: $\delta_{\mathrm{H}} 5.32, \mathrm{~J}_{1,2} 7.8 ; 6 \mathrm{~b}: \delta_{\mathrm{H}} 5.3, \mathrm{~J}_{1,2}$ 7.7). One of the observed side-reactions is acetyl transfer to the acceptor, as previously observed. ${ }^{14} \mathrm{H}$ owever, selective removal of one $N$-acetyl group in compounds $\mathbf{6 a}, \mathbf{b}$ could be readily performed with sodium methanolate in methanol; ensuing 0 -acetylation afforded compounds $\mathbf{8 a}, \mathbf{b}$ in very high yield.
The best results in terms of overall yield and conveniency of the experimental procedures were obtained with N -trichloroethoxycarbonyl (Teoc) ${ }^{18}$-protected trichloroacetimidate $3^{15,19}$ as glycosyl donor; addition of catalytic amounts of TM SOTf ( 0.01 mol equiv.) afforded, with acceptors $\mathbf{4 a}, \mathbf{b}$, the $\beta$-glycosides $7 \mathrm{a}, \mathrm{b}$ in $80 \%$ yield (1-H: 7a: $\delta_{\mathrm{H}} 4.61, \mathrm{~J}_{1,2} 8.3 ; 7 \mathrm{~b}: \delta_{\mathrm{H}} 4.53, \mathrm{~J}_{1,2} 8.1$ ). Direct replacement of the N -Teoc group by the N -acetyl group, by treatment with zinc in acetic anhydride, ${ }^{15 b}$ gave compounds 8a,b in $85 \%$ yield; therefore, this method seemed to be suitable for the direct generation of $0-\mathrm{GICNA}$ c-containing active esters of serine and threonine.
To this aim, glycosyl donor $\mathbf{3}$ was treated under the same reaction conditions with $\mathrm{N}^{a}-\mathrm{F}$ moc-protected serine and threonine allyl esters $9 \mathbf{a}, \mathbf{b}^{20}$ (Scheme 2), thus permitting manipulations ${ }^{7,8}$ of the product's orthogonal protective group in the presence of an 0 -acetyl-protected GICNA c residue. The desired $\beta$-glycosides 10a,b were obtained in this reaction in very high yield (1-H:10a: $\delta_{\mathrm{H}} 4.7, \mathrm{~J}_{1,2} 8.4 ; 10 \mathrm{~b}: \delta_{\mathrm{H}} 4.7, \mathrm{~J}_{1,2} 8.1$ ); again, transformation into target molecules, compounds 11a,b, could be readily performed with zinc in acetic anhydride. This result encouraged us to use directly $\mathrm{N}^{\mathrm{a}}$-F moc-protected serine and threonine Pfp esters 12a,b, ${ }^{21}$ typical active esters, as glycosyl acceptors; again, with Teoc derivative $\mathbf{3}$ in the presence of catalytic amounts of TM SOTf ( 0.01 mol equiv.) the serine $\beta$-glycoside 13a was obtained in $87 \%$ yield and the threonine $\beta$-glycoside 13b in $80 \%$ yield, respectively (1-H: 13a: $\delta_{\mathrm{H}} 4.67, \mathrm{~J}_{1,2}$ 8.2; 13b: $\delta_{\mathrm{H}} 4.72, \mathrm{~J}_{1,2} 8.1$ ). Their treatment with zinc in acetic anhydride furnished cleanly the target molecules 14a,b in 83 and $80 \%$ yield, respectively.
In conclusion, based on N -Teoc-protected trichloroacetimidate $\mathbf{3}$ as glycosyl donor, which is very readily available

from glucosamine, ${ }^{15} \beta$-linked $0-\mathrm{GIcNAc}$ serine and threonine derivatives can be efficiently obtained. M ost importantly, the corresponding $\mathrm{N}^{\mathrm{a}}$-F moc-protected Pfp active esters, which can be successfully employed in solid-phase glycopeptide synthesis, ${ }^{4,5,22}$ are also directly and efficiently accessible via this approach.

${ }^{1}$ H N M R spectra were measured with a Bruker AC 250 M Hz or a Bruker Avance DRX 600 M Hz spectrometer, with tetramethylsilane as internal standard for solutions in deuteriochloro-
form, unless otherwise stated. J -Values are given in $\mathrm{Hz} .{ }^{13} \mathrm{C}$ NM R spectra were taken on a Bruker AC ( 62.68 MHz ) spectrometer with ${ }^{13} \mathrm{CDCl}_{3}$ as internal standard ( $\delta_{\mathrm{c}} 77.0$ ) for solutions in deuteriochloroform. For all compounds the assignment of ${ }^{1} H$ NMR spectra was based on chemical-shift correlation (COSY) spectra. The assignment of ${ }^{13} \mathrm{C}$ NMR spectra were based on carbon-proton shift-correlation spectra (HMQC). M ass spectra were measured with a K ratus C ompact M ALDI 1 V5.2.0. Optical rotations were recorded on a Perkin-Elmer 241 polarimeter, and $[a]_{\mathrm{D}}$-values are given in $10^{-1}$ deg $\mathrm{cm}^{2} \mathrm{~g}^{-1}$. TLC was performed on M erck silica gel $60 \mathrm{~F}_{254}$ with detection by charring in sulfuric acid and by UV light when applicable. The silica gel used in column chromatography was M erck 60A, 230400 mesh. The silica gel used for purification of Pfp esters was dried for at least 6 h at $200^{\circ} \mathrm{C}$ prior to use, and ethyl acetate for the same purpose was dried over $3 \AA$ molecular sieves for 24 h prior to use. Dichloromethane was distilled from $\mathrm{CaH}_{2}$ and was stored over molecular sieves $3 \AA$ under argon. Concentration were performed under reduced pressure at temperatures $<40^{\circ} \mathrm{C}$. M ps were measured on a G allenkamp melting point apparatus and uncorrected. Light petroleum refers to the fraction with distillation range $35-65{ }^{\circ} \mathrm{C}$.

Compound 5 a ( $0.42 \mathrm{~g}, 0.5 \mathrm{mmol}$ ) was dissolved in 10 ml of the solvent mixture $\mathrm{CH}_{3} \mathrm{CN}$-tetrahydrofuran (THF)-EtOH ( $2: 1: 1$ ). To this mixturewas added ethylenediamine ( $60.7 \mu \mathrm{l}, 0.9$ mmol ) and the mixture was heated at $60^{\circ} \mathrm{C}$ for 6 h . The excess of reagent and solvent were removed under reduced pressure and the residue was treated with pyridine ( 5 ml ) and acetic anhydride ( 2 ml ) for 6 h at room temperature. The mixture was dissolved in ethyl acetate ( 20 ml ) and washed successively with water and saturated aq. sodium hydrogen carbonate. The organic layer was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, concentrated and purified by flash chromatography [ethyl acetate-light petroleum (3:7)] to afford title compound $8 \mathrm{a}(0.2 \mathrm{~g}, 65 \%)$. Compound 8 a was also prepared from substrates 6 a and 7 a as follows: compound $6 \mathrm{a}(0.33 \mathrm{~g}, 0.5 \mathrm{mmol})$ was dissolved in dry methanol ( 5 ml ). To this solution was added NaOM e ( 1 m solution in methanol) until the pH reached 8.5. The mixture was stirred for 1 h at room temperature, deionized with IR $120\left(\mathrm{H}^{+}\right)$resin, filtered, and concentrated under reduced pressure The residue was dissolved in pyridine ( 5 ml ) and acetic anhydride ( 2 ml ) was added dropwise.
