Intramolecular Diels-A Ider additions of the 2-benzopyran-3-ones 2 d , 2 e and 2 f with an E-SO $\mathbf{2}_{\mathbf{2}} \mathrm{Ph}$ substituent on the dienophile ( $\mathrm{X}=\mathrm{SO}_{2} \mathrm{Ph}$ in 2 ) show greatly enhanced exo-addition of the tether than is shown in the absence of the $\mathrm{E}-\mathrm{SO}_{2} \mathrm{Ph}$ group ( $\mathrm{X}=\mathrm{H}$ in 2). For 2 e and 2 f , exo-chain addition becomes preferred, and for 2d, endo-chain addition much less preferred, than in related cases with $X=H$. A n $\mathrm{E}-\mathrm{CO}_{2} \mathrm{M}$ e group on the dienophile is also effective in enhancing ex o-chain addition, but less effective than an $\mathrm{E}-\mathrm{SO}_{2} \mathrm{Ph}$ group. The adducts 4 e and 4 f undergo reductive elimination ( $5 \% \mathrm{Na}-\mathrm{Hg}$ ) to give the diterpene related products 32 and 33 respectively.

A though simple o-quinodimethanes like 1 ( $\mathrm{n}=0$ or 1 ) undergo predominant exo-selective Diels-A Ider reactions to give transBC fused products (Scheme 1), ${ }^{2}$ we found that related addition

Scheme 1
in 2-benzopyran-3-ones $\mathbf{2}(\mathrm{X}=\mathrm{H})$ gave mostly the product $\mathbf{3}$ of endo-chain addition (Scheme 2). ${ }^{\text {1b }}$
The products $\mathbf{3}$ with a cis-BC ring fusion were unsuitable for the synthesis of pisiferic acid $\mathbf{5}^{\mathbf{3}}$ and related diterpenoids (e.g. carnosol ${ }^{4}$ and taxodione ${ }^{5}$ ) which had been one of our goals in exploring the intramolecular Diels-A Ider (IM DA ) reactions of 2-benzopyran-3-ones. ${ }^{1 \mathrm{~b}}$ The different behaviour of $\mathbf{1}$ and $\mathbf{2}$ is most simply attributed to repulsion between the bridging $-\mathrm{C}(0) \mathrm{O}$ - moiety in $\mathbf{2}$ and an exo oriented tether. M oreover, steric clash with the pyrone ring A must be less significant than that with the $-\mathrm{C}(\mathrm{O}) \mathrm{O}-$ group. $\dagger$ This agrees with theoretical calculations on the addition of butadiene to ethylene ${ }^{8}$ which suggest a product-like transition state rather than a parallel planes approach of the diene and dienophile. A s a consequence there is closest approach between an exo directed hydrogen on the ethylene and the proximate $Z$-hydrogen of the diene. Whilst the detailed geometry of the Diels-Alder transition state will no doubt vary with the substituents on the diene and dienophile it seems likely that interaction between an exo-dienophile substituent and the proximate Z -substituent on the diene will remain an important factor in determining endo- exo selectivity. A ccordingly we argued that if group X in $\mathbf{2}$ was bulky, its steric clash with the - $\mathrm{C}(\mathrm{O}) \mathrm{O}$ - moiety in an endo-chain addition would favour an exo-chain, endo-X transition state It is noteworthy that in simple decatrienes 6 (Scheme 3) in which the Zpositions of the diene are occupied by hydrogens, a bulky E$\mathrm{SO}_{2} \mathrm{Ph}$ group on the dienophile favours the exo-position pre-
$\dagger$ The preferred endo-chain additions observed when $X=H$ echoes the strong endo-selectivity in the addition of cyclopentene to the parent 2-benzopyran-3-one. ${ }^{6}$ In both the intramolecular and the intermolecular reactions repulsion involving the lactone $C(0) 0$ group is one important factor. The existence of a second factor favouring endo-addition is suggested by the endo-preference observed for addition of E- $\alpha$-cyano- and E - $\alpha$-methoxycarbonyl-o-quinodimethane to cyclopentene. This other factor may be a secondary M O-M O interaction (steric attraction). ${ }^{7}$

sumably due to greater steric interaction with the diene C-2-C-3 moiety in an endo- $\mathrm{SO}_{2} \mathrm{Ph}$ (exo-chain) transition state. ${ }^{9}$ This is a useful way of diverting the evenly balanced endo-exo (chain) preference in the IM DA reactions of decatrienes to obtain mostly cis ring fused products (Scheme 3) i.e. to achieve the opposite stereoselectivity to that required in the additions of the pyrones 2.

Because of its bulk and anticipated easy removal we chose the phenylsulfonyl group as X in an attempt to divert the

stereochemistry of IM DA addition within the pyrones 2a-c. Several routes were used to prepare the precursors (0formylphenylacetic acids) required to generate the pyrones 2 ( $\mathrm{X}=\mathrm{SO}_{2} \mathrm{Ph}$ ). A lkylation of 6-methoxyisochroman-3-one [K N $\left(\mathrm{SiM}_{3}\right)_{2}, \mathrm{THF}$-hexamethylphosphorous triamide (HMPT)] with the iodides 7a-c gave mixtures of the required monoalkylated products 8 with corresponding dialkylated products

that had to be removed by chromatography. ${ }^{1 b}$ A $n$ attempt to avoid dialkylation involved ethoxycarbonylation of 6 -methoxy-isochroman-3-one $\left[\left(\mathrm{CO}_{2} \mathrm{Et}\right)_{2}, \mathrm{NaH}\right.$, benzene, reflux] and gave 9 in $48 \%$ yield. Alkylation of 9 with 7a gave 10 ( $64 \%$ ) which was smoothly hydrolysed and decarboxylated to 8a (95\%). However the overall yield was inferior to that from direct alkylation of 6 -methoxyisochroman-3-one(~50\%).

Ozonolysis of the compounds $\mathbf{8 a}, \mathbf{8 b}$ and $\mathbf{8 c}$ gave the corresponding aldehydes 11a, 11b and 11c which upon addition of $\mathrm{PhSO}_{2} \mathrm{CH} \mathrm{H}_{2} \mathrm{Li}\left(\mathrm{THF},-78{ }^{\circ} \mathrm{C}\right)$ and dehydration of the resulting hydroxy sulfones ( $\mathrm{MeSO} \mathrm{I}_{2} \mathrm{Cl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{THF},-5^{\circ} \mathrm{C}, 30 \mathrm{~min}$ ) gave 12a, 12b and 12c. For 12a and 12b lactone ring opening $\left(\mathrm{K}_{2} \mathrm{CO}_{3}-\mathrm{H}_{2} \mathrm{O}-\mathrm{MeOH}\right.$, reflux, 1 h ), esterification with diazomethane and Swern oxidation then gave the methyl esters of the
required acids $\mathbf{1 3 a}$ and $\mathbf{1 3}$ b. The acids were than obtained by hydrolysis ( $\mathrm{K}_{2} \mathrm{CO}_{3}-\mathrm{H}_{2} \mathrm{O}-\mathrm{MeOH}$, reflux, 1 h ).
A n attempt to open the lactone ring in 12c foundered due to a more rapid intramolecular $M$ ichael addition. A fter a workup involving acidification at $0-5^{\circ} \mathrm{C}$ and reaction with diazomethane, the cis-trans isomers corresponding to structure 14 were isolated as well as $24 \%$ of the desired hydroxy ester. This suggests faster closure of five- compared to six-membered rings via $M$ ichael addition although both these ring sizes are readily obtained via such additions. ${ }^{10}$ In seeking other routes to structures like 13c we found that the problem of dialkylation experienced with isochroman-3-ones [K N (SiM e $\mathrm{e}_{2}$, THF-HM PT $\left.)\right]^{\text {lb }}$ disappeared when the ethylene acetal of ethyl 0 -formylphenylacetate was alkylated with $7 \mathbf{7 a}$ and $\mathbf{7 c}$ under the same conditions; the monoalkylated products $\mathbf{1 6}$ and $\mathbf{1 7}$ were obtained in 60 and $53 \%$ yield respectively. U pon base hydrolysis these gave the ethylene acetals of acids 18 and 19 which readily underwent acid-catalysed hydrolysis to 18 and 19. Reaction of the ethylene acetal of 19 with $\mathrm{PhSeSO}_{2} \mathrm{Ph}$ (irradiation with a water-cooled 125 W medium pressure mercury lamp) ${ }^{11}$ and subsequent $\mathrm{H}_{2} \mathrm{O}_{2}$ oxidation-selenoxide elimination of the resulting selenosulfones gave the $\alpha, \beta$-unsaturated sulfone 20; acid hydrolysis then gave 13c. In a related, but not identical, sequence ester 16 underwent selenosulfonation-selenoxide elimination to give the ethyl ester of 21 which underwent acetal hydrolysis (THF-$\mathrm{HCl}-\mathrm{H}_{2} \mathrm{O}$ ), followed by ester hydrolysis ( $\mathrm{K}_{2} \mathrm{CO}_{3}-\mathrm{M} \mathrm{eOH}-\mathrm{H}_{2} \mathrm{O}$ ), to give acid 13d.
A $n$ attempt was made to introduce the intact $\alpha, \beta$-unsaturated sulfone side chain by reacting 7d with $\mathbf{1 5}\left[\mathrm{KN}\left(\mathrm{SiM} \mathrm{e}_{3}\right)_{2}, \mathrm{THF}-\right.$ HM PT]. The compound 7d was prepared from the TBDMS ether of pent-4-en-1-ol using selenosulfonation-selenoxide elimination (see Experimental section). U nfortunately reaction of $\mathbf{7 d}$ with $\mathbf{1 5}$ gave two products neither of which was the required mono-alkylation product. After hydrolysis of the acetal one product had ${ }^{1} \mathrm{H}$ NMR spectral characteristics consistent with structure $\mathbf{2 2}$ derived by Michael addition of the anion from $\mathbf{1 5}$ to give $\mathbf{2 3}$ followed by intramolecular displacement of iodide ion, as shown by the mechanism in 23, and acetal hydrolysis. There are precedents for this behaviour involving $\alpha, \beta$-unsaturated carbonyl compounds. ${ }^{12}$ In the present case $M$ ichael addition to the $\alpha, \beta$-unsaturated sulfone is clearly more rapid than $\mathrm{S}_{\mathrm{N}} 2$ displacement of iodide.
The other product from this reaction does not have ${ }^{1} \mathrm{H}$ NM R spectral characteristics consistent with structure 24 derived from the desired product via intramolecular M ichael addition (25; mechanism) and acetal hydrolysis. This product was subjected to careful chromatography but was never obtained completely pure The high field resonances and proton-proton connectivity (COSY) shown by the product are consistent with structure 26. Presumably 7d is deprotonated and its anion undergoes rapid ring closure to the cyclopropane 27 which subsequently adds to the anion of $\mathbf{1 5}$ in a M ichael reaction.
Reaction of the aldehyde 11a with the sodium salt of trimethyl phosphonoacetate gave the $\alpha, \beta$-unsaturated ester 28. U pon lactone ring opening, acidification at $0-5^{\circ} \mathrm{C}$ and methylation with diazomethane 28 gave the diester 29. Swern oxidation gave the aldehyde 30 and a remarkably selective hydrolysis of this diester with $\mathrm{K}_{2} \mathrm{CO}_{3}-\mathrm{MeOH}-\mathrm{H}_{2} \mathrm{O}$ at $20^{\circ} \mathrm{C}$ ( 1 h ) gave the required aldehydo acid 31.

In boiling acetic anhydride the acids 13a, 13b and 13c underwent smooth dehydration to pyrones as indicated by the formation of yellow colours which faded with formation of the adducts of type $\mathbf{3}$ and $\mathbf{4}$. A $s$ described in our earlier paper ${ }^{1 b}$ the ${ }^{1} \mathrm{H}$ N M R spectra of adducts of this type provide excellent evidence for their stereochemistry. The spectra upon which our current assignments are based are detailed in the Experimental section.

The ratios for endo-exo addition of the connecting chain observed for the compounds with an E-sulfonyl substituted dienophile are collected in Table 1 (entries 4-6) together with

data for related compounds lacking the phenylsulfonyl group (entries 1-3). In entry 7 the effect of an $\mathrm{E}-\mathrm{CO}_{2} \mathrm{M}$ e group on the dienophile is determined. All ratios were obtained from well resolved ${ }^{1} \mathrm{H} N \mathrm{~N}$ R spectra ( 400 MHz ) of the unpurified reaction product. Chromatographic isolation of the adducts agreed with these ratios. Y ields in the reactions were usually $>80 \%$. It is clear that in all the cases examined the endo- exo (chain) ratio is much reduced in the $\mathrm{E}-\mathrm{SO}_{2} \mathrm{Ph}$ compounds. For the pyrones with $\mathrm{n}=1$ (four atoms in the tether) the $\mathrm{E}-\mathrm{SO}_{2} \mathrm{Ph}$ group gives mostly the exo-chain adduct whereas in the absence of the $\mathrm{E}-\mathrm{SO}_{2} \mathrm{Ph}$ group the endo-chain adduct is dominant (cf. entry 2 vs. 5 and entry 1 vs. 6). Entry 7 shows the $\mathrm{E}-\mathrm{CO}_{2} \mathrm{M}$ e group is somewhat less effective in inducing the same change in stereochemistry, suggesting a steric rather than a secondary $\mathrm{M} \mathrm{O-M} \mathrm{O}$ interaction effect for the sulfones.

| 2 | $\mathbf{2 b}$ | $4.5: 1$ |
| 3 | $\mathbf{2 c}$ | $7.0: 1$ |
| $\mathbf{4}$ | $\mathbf{2 d}$ | $1.4: 1$ |
| $\mathbf{5}$ | $\mathbf{2 e}$ | $1.0: 4.2$ |

For the pyrones with three atoms in the tether ( $\mathrm{n}=0$ ) the effect of introducing an $\mathrm{SO}_{2} \mathrm{Ph}$ group is smaller but still well defined (entries 3 and 4). When the tether is longer ( $n=1$ ) the addition transition state is likely to involve greater synchrony of bond formation at the $\alpha$ and $\beta$ positions of the $\alpha, \beta$-unsaturated sulfone than when $n=0$. In the latter case, bond formation at the $\beta$-carbon is likely to run ahead of that at the $\alpha$-carbon. Consequently steric effects due to the $\mathrm{SO}_{2} \mathrm{Ph}$ group at $\mathrm{C}-\alpha$ will be less keenly felt in the transition state for the shorter tether.
Having served its purpose, the phenylsulfonyl group can be removed from $\mathbf{4 e}$ and $\mathbf{4 f}$ by treatment with $5 \%$ sodiumamalgam, when reductive $\beta$-elimination with the lactone in the manner of a Julia reaction provides the carboxylic acids 32 and 33 in good yield ( $>80 \%$ ). In these cases the trans coplanar

$32 \mathrm{R}=\mathrm{H}$
$33 \mathrm{R}=\mathrm{Me}$

34

35
arrangement of the eliminated groups leads to smooth reaction. In contrast, reaction of $3 \mathbf{e}$ with sodium-amalgam gave mostly the saturated sulfone 34 ( $57 \%$ ) and only $30 \%$ of the acid 35. This failure is not of preparative significance as compounds like $\mathbf{3 5}$ are easily prepared via acid catalysed elimination of the readily available endo-chain adducts $3(\mathrm{X}=\mathrm{H}) .^{\text {1b }}$
In conclusion, we have shown that IM DA additions to 2-benzopyran-3-ones $\mathbf{2}$ allow preparation of either cis- or transfused hydrophenanthrenes related to natural diterpenoids. Our results may extend to other dienes linked between their termini. Such systems include important Diels-A Ider dienes like cyclopentadienes, cyclohexadienes, furans, simple pyrones and other o-quinodimethanes. We also suggest that any diene with a Zsubstituent will show an increased tendency to endo-addition of the larger group of a trans-dienophile in both inter- and intra-molecular addition. Indeed this may explain why o-quinodimethanes with a Z-cyano group break the general rule of exochain preference in IM DA additions to 0-quinonoid dienes. ${ }^{13}$

## E thoxycarbonylation of 6-methoxyisochroman-3-one

To a stirred solution of sodium hydride ( 1.27 g , of a $60 \%$ dispersion in mineral oil, 31.7 mmol ) in benzene ( 20 ml ) was added diethyl carbonate ( $2.65 \mathrm{~g}, 22.4 \mathrm{mmol}$ ) in benzene ( 5 ml ). The reaction mixture was heated at reflux and a solution of 6 -methoxyisochroman-3-one ( $2.0 \mathrm{~g}, 11.2 \mathrm{mmol}$ ) in benzene ( 16 ml ) was added dropwise over 2.5 h and the reaction was heated at reflux ( 3 h ). The contents of the flask were cooled to room temperature and glacial acetic acid ( 16 ml ) was added dropwise followed by water ( 8 ml ) and the reaction was stirred at $20^{\circ} \mathrm{C}$ ( 15 h ). The solution was poured into water, extracted with dichloromethane, dried $\left(\mathrm{M}_{\mathrm{gSO}}^{4}\right.$ ) and concentrated to give an oil ( 2.54 g ). Chromatography on silica ( 80 g ) eluting with dichloromethane gave the ethyl 6 -methoxy-3-oxochromane-4carboxylate 9 ( $1.34 \mathrm{~g}, 48 \%$ ) (Found: C, 62.5; H,5.7. The solution was cooled to room temperature and a solution of the iodide 7a ( $111 \mathrm{mg}, 0.53$ $\mathrm{mmol})$ in DM F ( 2 ml ) added. The mixture was heated at 55$60^{\circ} \mathrm{C}$ (bath temperature) ( 16 h ) then diluted with ether, washed with water $(240 \mathrm{ml})$, dried $\left(\mathrm{M} \mathrm{gSO}_{4}\right)$ and concentrated to give an oil. ## Hydrolysis of 10

The title compound ( $71 \mathrm{mg}, 0.21 \mathrm{mmol}$ ), potassium carbonate ( $59 \mathrm{mg}, 0.43 \mathrm{mmol}$ ), methanol $(2.2 \mathrm{ml}$ ) and water ( 1.1 ml ) were
heated at $50^{\circ} \mathrm{C}$ (bath temperature) ( 6 h ). The mixture was acidified to pH 1 with dilute hydrochloric acid ( $2 \mathrm{~mol} \mathrm{dm}{ }^{-3}$ ), extracted with ether, washed (water), dried ( $\mathrm{M} \mathrm{gSO}_{4}$ ) and concentrated. The crude product was heated on a steam bath $\left(100^{\circ} \mathrm{C}\right)(10 \mathrm{~min})$ to give the decarboxylated product $8 \mathrm{a}(52 \mathrm{mg}$, $95 \%$ ). The ${ }^{1} \mathrm{H}$ NMR spectrum of the product was identical to that of a previously prepared sample ${ }^{\text {1b }}$

## Preparation of the aldehyde 11a

The olefin $8 \mathrm{a}(2.0 \mathrm{~g}, 7.69 \mathrm{mmol})$ was dissolved in dry dichloromethane ( 27 ml ) and dry methanol ( 40 ml ) and ozonolysed at $-78^{\circ} \mathrm{C}(0.5 \mathrm{~h})$. Dry argon was bubbled through the solution ( 1 h ) and dimethyl sulfide added. Then the solution was allowed to reach room temperature with stirring (3 h). Chromatography of the evaporated product on silica ( 40 g ) in benzene-ether (7:3) gave 4-(5-oxopentyl)-6-methoxychroman-3-one 11a (1.53 $\mathrm{g}, 76 \%$ ) as an oil (Found: $\mathrm{C}, 68.9 ; \mathrm{H}, 6.8 . \mathrm{C}_{15} \mathrm{H}_{18} \mathrm{O}_{4}$ requires C , $68.7 ; \mathrm{H}, 6.9 \%) ; v_{\text {max }}$ (film)/ $\mathrm{cm}^{-1} 2740,1740$ and 1730; $\delta_{\mathrm{H}}(300$ $\mathrm{MHz}) 1.54(2 \mathrm{H}, \mathrm{m}), 1.70(2 \mathrm{H}, \mathrm{m}), 1.87(1 \mathrm{H}, \mathrm{m}), 1.98(1 \mathrm{H}, \mathrm{m})$, $2.49(2 \mathrm{H}, \mathrm{t}, \mathrm{J} 7.0$, methylene-H ), $3.56(1 \mathrm{H}, \mathrm{t}, \mathrm{J} 7.0$, methine-H ), 3.83 ( $3 \mathrm{H}, \mathrm{s}, \mathrm{OM} \mathrm{e}$ ), 5.21 ( 1 H , d, J 14.0, benzylic-H ), 5.38 ( 1 H , d, J 14.0, benzylic-H ), 6.73 ( $1 \mathrm{H}, \mathrm{s}, \mathrm{Ar}-\mathrm{H}$ ), 6.82 ( $1 \mathrm{H}, \mathrm{dd}, \mathrm{J} 8.5$ and 2.0, Ar-H ), 7.14 ( $1 \mathrm{H}, \mathrm{d}, \mathrm{J} 8.5, \mathrm{Ar}-\mathrm{H}$ ) and 9.77 ( $1 \mathrm{H}, \mathrm{s}, \mathrm{CHO}$ ); $\mathrm{m} / \mathrm{z} 262\left(\mathrm{M}^{+}\right), 177,149,83,70,57,56,55,43$ and 41 (29.3, 22.7, $22.7,23.3,23.5,100.0,22.7,28.6,36.9$ and $42.2 \%$ ).

The acetal in THF ( 1 ml ), water ( 1 ml ) and 2 m hydrochloric acid (1 ml ), were stirred under argon (2 h), extracted into ether and washed with water, dried $\left(\mathrm{M} \mathrm{SO}_{4}\right)$ and evaporated under reduced pressure to give an orange oil. Chromatography on silica ( 25 g ) in benzene-ether ( $9: 1$ ) gave the impure cyclopropane derivative 26 as a pale yellow oil ( $8 \mathrm{mg}, 4 \%$ ); $v_{\text {max }}($ film $) /$ $\mathrm{cm}^{-1} 1738$ and $1700 ; \delta_{\mathrm{H}}(300 \mathrm{M} \mathrm{Hz})-0.03(1 \mathrm{H}, \mathrm{m}), 0.165(1 \mathrm{H}$, $\mathrm{m}), 0.30-0.35(2 \mathrm{H}, \mathrm{m}), 1.15(1 \mathrm{H}, \mathrm{m}), 1.21(3 \mathrm{H}, \mathrm{t}, \mathrm{J} 7.0), 2.04$ (1H , m), 3.22 ( $1 \mathrm{H}, \mathrm{dd}, \mathrm{J} 5,14.5$ ), 3.35 ( $1 \mathrm{H}, \mathrm{dd}, \mathrm{J} 14.5,5.5$ ), 4.1$4.2\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CO}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 5.23(1 \mathrm{H}, \mathrm{d}, \mathrm{J} 8.0), 7.3-7.9(9 \mathrm{H}, \mathrm{m}$, A r-H ) and 10.31 ( $1 \mathrm{H}, \mathrm{s}, \mathrm{CH} 0$ ); the COSY spectrum established coupling of the protons at the following resonances: $\delta 5.23$ to 2.04; 2.04 to $5.23,3.22,3.35$ and $1.15 ; 1.15$ to $2.04,0.3-0.5$, 0.165 and $-0.03 ; \mathrm{m} / \mathrm{z} 527\left(\mathrm{M}^{+}\right), 389,258,184,118$ and 77 (1, $37,36,46,77$ and $100 \%)$. F urther elution of the column gave ethyl $\quad 2$-(2-formylphenyl)-2-(2-phenylsulfonylcyclopent-1-yl)acetate 22 ( $80 \mathrm{mg}, 47 \%$ ) (Found: $\mathrm{M}^{+}, 400.1344 . \mathrm{C}_{22} \mathrm{H}_{24} \mathrm{SO}_{5}$ requires $\mathrm{M}, 400.1342$ ); $v_{\text {max }}($ film $) / \mathrm{cm}^{-1} 1733,1698,1308$ and $1148 ; \delta_{\mathrm{H}}\left(\mathrm{C}_{6} \mathrm{D}_{6}, 300 \mathrm{M} \mathrm{Hz}\right) 0.73(3 \mathrm{H}, \mathrm{t}, \mathrm{J} 7), 1.75(3 \mathrm{H}, \mathrm{m}), 2.01$ $(1 \mathrm{H}, \mathrm{m}), 2.30(2 \mathrm{H}, \mathrm{m}), 3.22(1 \mathrm{H}, \mathrm{m}), 3.49(1 \mathrm{H}, \mathrm{m}), 3.80(2 \mathrm{H}, \mathrm{m}$, $\left.\mathrm{CO}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}\right), 5.28(1 \mathrm{H}, \mathrm{d}, \mathrm{J} 10), 6.75(5 \mathrm{H}, \mathrm{m}, \mathrm{Ar}-\mathrm{H}), 7.10(1 \mathrm{H}$, $\mathrm{m}, \mathrm{Ar}-\mathrm{H}), 7.30\left(1 \mathrm{H}, \mathrm{m}, \mathrm{SO}_{2} \mathrm{Ph}\right), 7.55\left(2 \mathrm{H}, \mathrm{m}, \mathrm{SO}_{2} \mathrm{Ph}\right)$ and 9.78 (1H, s, CHO); m/z $400\left(\mathrm{M}^{+}\right), 399,353,211,184,166,157,91$ and $77(2,6,65,100,92,83,52,61$ and $90 \%)$.
