Reaction of diisobutylaluminium hydride with selenium and tellurium: new reagents for the synthesis of seleno- and telluro-amides

Guang Ming Li* and Ralph A. Zingaro

Department of Chemistry, Texas A & M University, College Station, TX 77843-3255, USA

Diisobutylaluminium hydride (Bu_2^iAIH) undergoes reaction with elemental selenium and tellurium to afford new reagents having an Al–Se or an Al–Te bond. These directly convert amides to selenoamides and telluroformamides. This affords a one-pot route to selenoamides and telluroformamides starting from Se and Te, and may be suitable for large scale syntheses.

Introduction

Selenoamides have proved to be useful compounds in organic transformations and several methods for their preparation have been reported.¹ There has been a considerable interest in their tellurium analogs, viz., telluroamides, with respect to their syntheses, structures and reactivities. Telluroamides, like other tellurocarbonyl compounds, are difficult to prepare due to the instability of the C=Te bond. To date, only a very limited number of telluroamides² and their first metal complexes³ have been described. Among currently active studies in the field of organo-selenium and -tellurium chemistry,4 bis(dimethylaluminium) selenide and telluride, (Me₂Al)₂E where E is Se or Te, have been found to be effective reagents for the conversion of carbonyl groups to seleno- and tellurocarbonyls (C=E).^{2b,c,5} Using this procedure, we have successfully synthesized two telluroamides and determined their crystal structures.^{2c} In this paper,⁶ we report a one-pot synthesis of seleno- and telluro-amides by the reaction of amides with some new Al-Se and Al-Te reagents (Scheme 1). These reagents are prepared by the reaction between diisobutylaluminium hydride and selenium or tellurium powders. They are obtained as a mixture of $(Bu_2^iAlE)_2$ and $(Bu^iAlE)_n$ where E is Se or Te.

Results and discussion

Under an argon atmosphere, a mixture of Bu_2^iAlH (1.5 M) solution in toluene, 10 ml, 15 mmol) and one equivalent of powdered selenium or tellurium was heated at 120–130 °C for 1–2 h. All of the Se or Te was dissolved. There was first produced a clear colorless solution⁷ in the case of Se, which subsequently converted to a white suspension when cooled below 90 °C. A white suspension⁷ was obtained when Te was used. During the heating, gaseous evolution was observed.⁸ Mass spectrometry confirmed that the gases were hydrogen and isobutane which indicated the formation of dimer $(Bu_2^iAlE)_2$ and oligomer $(Bu^iAlE)_n$.

The products obtained in the reaction between Se and Buⁱ₂AlH were characterized by NMR spectrometry. In the ¹H spectra, compared with Buⁱ₂AlH, the reaction mixture exhibited resonances at the same region except for the presence of a small doublet at δ 2.65 ppm arising from the CH₂ bonded to Se. This indicates that only a small amount of selenium inserts into the C–Al bond of Buⁱ₂AlH to form C–Se–Al type compounds. Most of the selenium inserts between aluminium and the hydride hydrogen. Seven doublets for methyl and methylene protons of Buⁱ groups appeared in the ¹H NMR spectra, and eight different carbon resonances were observed in the ¹³C NMR spectra (Fig. 1). The relatively complicated

(BuⁱAlE). toluene NR¹R² Buⁱ2AlH (Buⁱ2AlE)2 Ε toluene 1-15 C-E-Al type E = Se, Te5 Мe 12 10 11 Ph 13 14 15 Scheme 1

¹H and ¹³C NMR spectra are due to the presence of a mixture of several Al–Se compounds formed in the reaction. In the ⁷⁷Se NMR spectra (in C₆D₆–toluene), two peaks (δ –184.53, –263.37 ppm) were observed. They arise from two different Al–Se compounds, (BuⁱAlSe)_n and (Buⁱ₂AlSe)₂. These shifted to δ –211.64 and –430.27 ppm when THF was added.⁹

These results suggest that the reaction between diisobutylaluminium hydride and selenium and tellurium produces a mixture of $(Bu_2^iAIE)_2$ and $(Bu^iAIE)_n$ (E is Se or Te) together with a small amount of C–E–Al type compounds.

Owing to their instability, toxicity, and extremely unpleasant

odor, these reagents were neither purified nor fully characterized. We have begun to investigate their reactivities. As listed in Table 1, these reagents prepared *in situ* undergo reaction with amides and efficiently convert them to seleno- and telluroamides 1–15. In addition, $Bu_2^iE_2$, which was identified by ¹H NMR and mass spectrometry, was isolated in all cases in 5–10% yields.⁷ Compounds 2, 4, 6, 7, 12 and 14 are the same as those obtained with the use of (Me₂Al)₂E.^{2b,c,3} All selenoamides gave the expected NMR (¹H, ¹³C, ⁷⁷Se), mass spectral and analytical

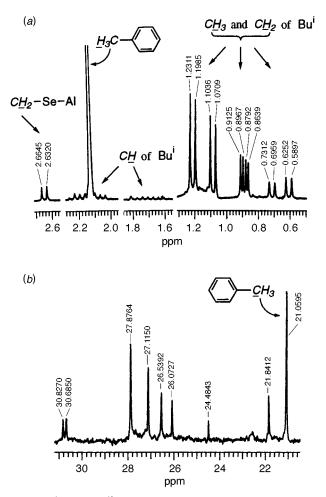

Fig. 1 (a) ¹H and (b) ¹³C NMR spectra of Al–Se reagents formed in the reaction of Bu_2^iAlH and Se (measured in C_6D_6 –toluene, 200.1 Hz for ¹H; 50.3 Hz for ¹³C)

Table 1 Preparation of seleno- and telluro-amides (1-15) from amides^a

data. Tellurium compounds (11–15) gave the expected spectral data, but because of decomposition during delivery they did not give acceptable elemental analyses. Seleno- and telluro-formamides (1–7 and 11–14) were isolated in yields of 49–69%. However, *N*,*N*-dimethyl(selenoacetamide) 8 and a γ -seleno-lactam, 1-methyl-2-selenoxopyrroline 10 were obtained in lower yields. *N*,*N*-dimethyl(selenobenzamide) 9 was isolated in only 30% yield, even under much more vigorous reaction conditions. All attempts to prepare *N*,*N*-dimethyl(telluroacetamide) and *N*,*N*-dimethyl(tellurobenzamide) were unsuccessful. This is probably because the CH₃ of *N*-acetyl or the Ph of *N*-benzoyl hindered the attack from Al–Se or Al–Te reagents into the carbonyl group.

Both the reagents described in this paper, $(Bu_2^iAIE)_2$ and $(Bu^iAIE)_n$ where E is Se or Te, and the closely related analog $(Me_2AI)_2E$ are good for the conversion of amides to selenoamides and telluroformamides. The former are much easier to prepare. The yields of selenoamides and telluroformamides obtained in the present work are generally lower than that prepared by the procedure using $(Me_2AI)_2E.^{2b,c}$ However, 4-(telluroformyl)morpholine (12) was obtained almost in the same yield: 66% in this work and 69.5% when $(Me_2AI)_2Te$ was used. In addition, $(Me_2AI)_2E$ compounds are useful for the preparation of selenoaldehydes, selenoketones, telluroaldehydes and telluroketones.⁵ Further investigations on the utilization of the reagents $(Bu_2^iAIE)_2$ and $(Bu^iAIE)_n$ are in progress.

In conclusion, the present procedure provides a convenient synthetic route for the preparation of a variety of selenoamides and telluroformamides, and can easily be adapted to large scale syntheses with proper safety precautions in handling large amounts of diisobutylaluminium hydride toluene solutions.

Experimental

General

THF was refluxed over potassium metal and distilled under argon prior to use. All other chemicals were used as received. ¹H and ¹³C NMR spectra were recorded on a Varian XL-200 spectrometer (200.1 MHz for ¹H, 50.3 MHz for ¹³C). ⁷⁷Se and ¹²⁵Te NMR spectra were measured on a Varian XL-200 broadband spectrometer (38.2 MHz for ⁷⁷Se, 63.1 MHz for ¹²⁵Te) with Ph₂Se₂ (δ 460 ppm referenced to Me₂Se)^{10a} or Ph₂Te₂ (δ 420.8 referenced to Me₂Te)^{10b} as the external standards. Mass spectra were run using a VG-70S spectrometer in the +FAB/DP or EI/DP mode. Melting points were determined on a Fisher-Johns melting point apparatus and are uncorrected. Elemental analyses were performed by Galbraith Laboratories,

General procedure for one-pot synthesis of selenoamides

A mixture of selenium (1.185 g, 15 mmol) and Bu_2^iAIH (1.5 m in toluene, 10 ml, 15 mmol) was heated at 120–130 °C for 1 h under argon, and then cooled to room temperature. To this, 15.5 mmol of the appropriate amide was added. The mixture was stirred under the conditions shown in Table 1. Following evaporation, the residue was chromatographed on Silica gel column with hexane followed by CH_2Cl_2 as the solvents.¹¹ Evaporation of the eluate gave the corresponding selenoamides.

General procedure for one-pot synthesis of telluroamides

In an aluminium-foil-wrapped, very dry, and air-free threenecked flask, tellurium (1.915 g, 15 mmol) and Bu_2^iAIH (1.5 m in toluene, 10 ml, 15 mmol) was stirred at 120–130 °C for 2 h. To this, 15.5 mmol of an amide was added at room temperature. The mixture was stirred at 20–30 °C for 3 h, and then evaporated. The telluroamide was isolated by flash column chromatography on Florisil with hexane followed by $\rm CH_2Cl_2$ as the solvents.¹¹
