#### Abstract

A synthetic strategy for the preparation of tetronasin 1, an acyltetronic acid ionophore demonstrating antibiotic, antiparasitic and growth promotion in ruminants is described. The key step involves a metal mediated cyclization reaction which creates two rings and four new stereocentres in a highly efficient manner. The configurations of three of these stereocentres are as required for the synthesis of tetronasin. The remaining stereocentre is readily epimerised to the natural configuration at a later stage of the synthesis.

Tetronasin (ICI M139603) 1, an acyltetronic acid ionophore

produced by Streptomyces longisporoflavus, ${ }^{1}$ is of commercial interest owing to its biological activity as an antibiotic, antiparasitic and growth promotion agent in ruminants. ${ }^{2}$ It has also attracted attention owing to its unusual structure ${ }^{1}$ and properties ${ }^{3}$ and has been the subject of extensive biosynthetic ${ }^{4}$ and synthetic studies. ${ }^{5}$

In terms of total synthesis, tetronasin $\mathbf{1}$ presents a significant challenge in that it contains twelve stereogenic centres, three different heterocyclic ring systems, two stereodefined alkenes and a triequatorially substituted cyclohexane unit. Furthermore, the acyltetronic acid group occurs in only a limited number of natural products, consequently there are relatively few methods available for its construction.

In the initial synthesis plan towards tetronasin $\mathbf{1}$ we propose to adopt a conceptually interesting approach involving a metal templated polyene cyclization reaction of an open chain precursor 2. It was hoped that metal chelation might encourage a favourable reacting conformation leading directly to an advanced polycyclic species $\mathbf{3}$ which could be further processed to $\mathbf{1}$ (Scheme 1). The required open chain precursor 2 in turn, could be assembled from readily prepared building blocks $4-8$ in a convergent fashion.

## Results and discussion

In previous studies we had shown that the stannyl tetronic acid fragment $\mathbf{4}$ was indeed an excellent precursor for acyltetronic acids and had completed the synthesis of three natural products, carlosic acid, carolinic acid and agglomerin A. ${ }^{6}$ In this
published work the tri-n-butyl stannyl group served as a suitable coupling component with acid chlorides under palladium catalysed conditions.

The stabilised Wittig reagent $\mathbf{5}$ is a known three carbon building block. ${ }^{7}$ The synthesis of the remaining fragments 6,7 and 8 are reported below, together with further coupling studies leading to the synthesis of tetronasin $\mathbf{1}$ itself.

The preparation of the phosphonate $\mathbf{6}$ could be readily achieved from the alcohol $9^{5 f}$ in a series of straightforward steps (Scheme 2).

Firstly $\mathbf{9}$ was converted to the corresponding tosylate $\mathbf{1 0}$ which was then coupled with the Grignard reagent derived from 5-bromopent-1-ene in the presence of $\mathrm{Li}_{2} \mathrm{CuCl}_{4}$ to afford the olefin 11. ${ }^{8}$ This in turn was subjected to ozonolysis followed by Lehnert modified Knoevenagel condensation ${ }^{9}$ of the resulting aldehyde $\mathbf{1 2}$ with triethylphosphonoacetate to give $\mathbf{1 3}$ as a mixture of the desired allyl and undesired vinyl isomers in a ratio of $4: 1$ in favour of the former isomer. Removal of the benzyl protecting group improved this ratio to $200: 1$ in favour of the allyl isomer, and subsequent treatment with TMSCl in the presence of triethylamine afforded the silyl protected phosphonate 6.

The keto phosphonate fragment 7 was also readily obtained from the same initial chiral alcohol 9. Firstly, conversion ${ }^{10}$ to the corresponding bromide $\mathbf{1 5}$ was necessary and this was followed by reaction of $\mathbf{1 5}$ with the dianion generated from dimethyl 2 -oxopropylphosphonate to give the required coupling component 7 in $56 \%$ overall yield (Scheme 3).
For the synthesis of the remaining tetrahydrofuran aldehyde fragment $\mathbf{8}$ we report two routes, both of which are efficient and allow access to multigramme quantities of material. We have previously published ${ }^{5 f}$ an earlier route to this material, but it is less amenable to scale up and is therefore not reported here.

Consistent with our synthesis plan to use common building blocks wherever possible, one route to $\mathbf{8}$ employs the chiral alcohol 9 , the use of which was reported earlier. Oxidation of 9 under Swern conditions ${ }^{11}$ followed by addition of ( $Z$ )-crotyl-$(+)$-diisopinocampheylborane ${ }^{12}$ and oxidative work-up gave 16 in which three of the required stereogenic centres are set up in place (Scheme 4). After standard protection as the tertbutyldimethylsilyl ether and hydroboration with 9-BBN, oxidative work-up followed by a Swern oxidation gave the aldehyde 19. This was homologated to the allylic ester 20 by reaction with

Tetronasin 1

Scheme 1
triethylphosphonoacetate under the Masamune-Roush conditions ${ }^{13}$ and subsequently reduced with diisobutylaluminium hydride in tetrahydrofuran in excellent overall yield.

The stage was now set to introduce the remaining two stereogenic centres via a Sharpless asymmetric oxidation procedure. ${ }^{14}$ Thus, reaction of 21 with titanium(Iv) isopropoxide, tertbutylhydroperoxide and (+)-diethyl tartrate gave the desired epoxide 22 (Scheme 4).

Deprotection of $\mathbf{2 2}$ with tetra- $n$-butylammonium fluoride in THF at $60^{\circ} \mathrm{C}$ resulted in concomitant intramolecular epoxide ring opening to provide the tetrahydrofuran 23 in $85 \%$ yield. The remaining steps in the synthesis were relatively straightforward and proceeded in equally high yields. Selective tosylation of the primary hydroxy group in $\mathbf{2 3}$ to give $\mathbf{2 4}$ was achieved
by reaction with dibutyltin oxide ${ }^{15}$ followed by toluene- $p$ sulfonyl chloride and triethylamine. This was then transformed to 26 by reduction with Super Hydride $\left(\mathrm{LiEt}_{3} \mathrm{BH}\right)$ and subsequent alkylation of the hydroxy group with methyl iodide and potassium hydride. Finally, deprotection with hydrogen using palladium on charcoal as catalyst, followed by oxidation with tetra- $n$-propylammonium perruthenate (TPAP) ${ }^{16}$ gave the required tetrahydrofuran aldehyde 8 (Scheme 4). This material was identical in all respects to that which we had prepared by the earlier route ${ }^{5 f}$ and to that obtained by natural product degradation. ${ }^{5 f}$

In the second route to aldehyde 8 (Scheme 5) we sought to exploit additional synthetic methodology developed in our laboratories ${ }^{17}$ for the formation of carbon-carbon bonds

adjacent to oxygen in cyclic ethers using 2-phenylsulfonyl derivatives.
Accordingly, the alcohol $\mathbf{2 8}^{5 f}$ was oxidised under Swern conditions ${ }^{11}$ and the aldehyde thus formed treated with ( $E$ )-crotyl-(-)-diisopinocampheylborane ${ }^{12}$ to afford the alkene 29 after work-up with diethanolamine. ${ }^{18}$ Deprotection of the silyl ether with TBAF afforded diol $\mathbf{3 0}$ with three of the required five stereogenic centres efficiently established. The diol $\mathbf{3 0}$ was next converted to the nitrile $\mathbf{3 2}$ by selective 2-mesitylenesulfonylation of the primary hydroxy group and displacement with sodium cyanide in $67 \%$ overall yield for these first four steps. The nitrile group in 32 was reduced with diisobutylaluminium hydride and the intermediate lactol treated with phenylsulfinic acid, using our previously established protocol, ${ }^{17}$ to afford the crystalline sulfone 34 in good yield. Sulfone 34 was then reacted with ethynylmagnesium bromide in the presence of zinc chloride at room temperature to afford stereoselectively the trans-substituted tetrahydrofuran 35. This was then hydrolysed with mercuric oxide and sulfuric acid ${ }^{19}$ to yield the corresponding acetyl derivative $\mathbf{3 6}$ in $71 \%$ yield from the sulfone 34. Finally, the carbonyl group in $\mathbf{3 6}$ was reduced with sodium borohydride in methanol at room temperature to afford a mixture of diastereomeric alcohols 37a and 37b ( $3: 2$ 37a:37b). Alternatively, reduction with L-Selectride ${ }^{20}$ in THF at $-78^{\circ} \mathrm{C}$ afforded exclusively alcohol 37a which could be readily inverted to the required isomer 37b using standard Mitsunobu ${ }^{21}$ reaction conditions. Methylation of alcohol 37b followed by ozonolysis of ether 38 afforded the furan fragment 8 . This second route to $\mathbf{8}$ is complementary to the first sequence, it provides efficient access to good quantities of 8, and, moreover, it employs methods developed by our group.

Now that all the key fragments as outlined in the initial plan for the synthesis of tetronasin $\mathbf{1}$ were available, their coupling and further processing could be investigated (Scheme 6).

Firstly we assembled the C-13 to C-26 unit by coupling the central keto phosphonate 7 with the terminal aldehyde group of the tetrahydrofuran fragment 8 using the previously described Masamune-Roush conditions ${ }^{13}$ to give the enone product 39 in a completely $(E)$-selective fashion with no detectable epimerization of the sensitive stereogenic centre adjacent to the aldehyde functionality. Reduction of the enone 39 with Noyori's $(S)$-BINAL-H reagent ${ }^{22}$ proceeded well to give the alcohol 40 with excellent control of the newly formed stereogenic centre. The minor amount of the unwanted diasteroisomer was readily inverted to give more 40 using the Mitsunobu procedure ${ }^{21}$ followed by hydrolysis in the normal way. The stereochemical outcome of this reduction reaction is in agreement with the model predicted by Noyori ${ }^{22}$ and also confirmed by the fact that it was later converted to the natural product itself. Following protection of $\mathbf{4 0}$ as its tert-butyldimethylsilyl ether 41 and

removal of the benzyl group with sodium in ammonia at $-33{ }^{\circ} \mathrm{C}$, the intermediate alcohol 42 was oxidised to the aldehyde 43 in $95 \%$ yield using catalytic TPAP ${ }^{16}$ and $N$-methyl-morpholine- $N$-oxide as cooxidant. Coupling of $\mathbf{4 3}$ to the next key fragment $\mathbf{6}$ in the proposed synthesis of $\mathbf{1}$ was best achieved using lithium hexamethyldisilazide in THF at $-78^{\circ} \mathrm{C}$ to deprotonate the ester phosphonate 6 which was then reacted with 43 and worked-up by treatment with a pH 3 buffer to give 45 in its deprotected form in excellent yield and with excellent stereochemical control. Many alternative conditions were investigated for this coupling but were much less successful, giving either mixtures of double bond isomers or causing racemisation of the stereogenic centre next to the aldehyde group in 43. Once again we found it most convenient to oxidise the hydroxy group in $\mathbf{4 5}$ to the aldehyde $\mathbf{4 6}$ using the TPAP reagent system which proceeded in $95 \%$ yield and with no detectable scrambling of the sensitive stereogenic centres.

Further homologation of 46 was achieved via a Wittig reaction followed by silyl deprotection with Dowex-50W in
methanol to give $\mathbf{4 8}$ as a pure product in excellent overall yield (Scheme 6).

Whilst compound 48 is a suitable material on the pathway to natural product tetronasin 1 based on our original synthesis plan, it also contains all the elements necessary to undergo a metal mediated polyene cyclization in its own right. Namely, the secondary hydroxy group is ideally placed to undergo a conjugate addition to the acceptor dienic ester unit which, via reequilibration of the resulting enolate, could undergo the second cyclization by Michael addition to the terminal methacrylate unit to assemble the cyclohexyl ring of the natural product in one operation. This attractive option was thus worthy of investigation in spite of the realization that we would be setting a tough challenge in forming two new rings and creating four new stereogenic centres simultaneously. Nevertheless, we felt confident that the natural conformation might lead to favourable transition states and hence to the double cascade cyclization reaction under appropriate conditions. Moreover, for various reasons, the product of this process might be more readily converted to tetronasin 1.

Although we investigated many conditions for this ambitious concept we were pleased to find that treatment of $\mathbf{4 8}$ with potassium hexamethyldisilazide in toluene at $0{ }^{\circ} \mathrm{C}$ gave a single product 49 in $67 \%$ yield!

What should be noticed in this reaction is that we do form the tetrahydropyran and cyclohexane rings with complete control, but the configuration of the C-4 (tetronasin numbering) methyl substituent is opposite to that found in tetronasin 1. The proof of configuration of this C-4 centre follows from extensive NMR investigation and later experiments. Other metal bases, solvents and temperature conditions used in this reaction were much less satisfactory, leading to either monocyclization or decomposition. We also investigated methods to install the correctly configured methyl substituent by later introduction via alkylation or by epimerisation of the C-4 stereogenic centre in 49 but without success.

In order to correct this stereochemical problem we devised an alternative sequence which proved to be very satisfactory. Firstly we found that the diester 49 could be selectively reduced to the alcohol $\mathbf{5 1}$ using lithium borohydride in THF to give $\mathbf{5 1}$ in $58 \%$ yield together with some of the diol $\mathbf{5 0}(19 \%)$ and a little ( $4 \%$ ) recovered starting material (Scheme 7). Reaction of 51 with tert-butyldimethylsilyl triflate gave the protected derivative 52 which upon treatment with diisobutylaluminium hydride in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ gave the differentiated diol $53(79 \%)$. This could then be oxidised to the aldehyde 54 using the Dess-Martin periodinane reagent. ${ }^{23}$ Although aldehyde $\mathbf{5 4}$ could not be epimerised under any base mediated conditions which we investigated, we found that epimerisation to the required aldehyde 55 could be achieved in $85 \%$ yield by simply refluxing the aldehyde 54 with morpholine and catalytic toluene-p-sulfonic acid (Scheme 7). This aldehyde 55 was identical in all respects to that prepared by Yoshii ${ }^{5 g}$ as a late stage precursor in their synthesis of tetronasin which involved reaction of 55 with $\mathrm{N}_{2} \mathrm{CHCO}_{2} \mathrm{CH}_{2}-$ $\mathrm{COOCH}_{3}$ in the presence of $\mathrm{ZrCl}_{4}$ to give the $\beta$-keto ester derivative 56. ${ }^{5 g}$ This, upon Dieckmann cyclization and deprotection using conditions first developed by our group involving tetra- $n$-butylammonium fluoride in THF, ${ }^{24}$ following work-up as the sodium salt gave the acyltetronic acid natural product tetronasin 1.

In summary we report above the concise formal synthesis of tetronasin 1, an important ionophore antibiotic using some of the methods and reagents developed in our laboratory.

DMSO ( $20 \mathrm{~cm}^{3}, 0.28 \mathrm{~mol}$ ) was added, followed by the dropwise addition of oxalyl chloride $\left(15 \mathrm{~cm}^{3}, 0.17\right.$ $\mathrm{mol})$. Stirring was continued for 10 minutes at $-78^{\circ} \mathrm{C}$, then a solution of the alcohol $9(20 \mathrm{~g}, 0.11 \mathrm{~mol})$ in dichloromethane $\left(100 \mathrm{~cm}^{3}\right)$ was added by cannula. The mixture was stirred at $-78^{\circ} \mathrm{C}$ for 1 hour, then triethylamine ( $40 \mathrm{~cm}^{3}, 0.32 \mathrm{~mol}$ ) was added. After stirring at $-78^{\circ} \mathrm{C}$ for 15 minutes, the mixture was
allowed to warm to room temperature and diluted with ether $\left(600 \mathrm{~cm}^{3}\right)$, washed with $2 \%$ aqueous $\mathrm{KHSO}_{4}\left(200 \mathrm{~cm}^{3}\right)$, water $\left(200 \mathrm{~cm}^{3}\right)$ and brine $\left(200 \mathrm{~cm}^{3}\right)$. The mixture was dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and evaporated to dryness. The resulting yellow oil was passed down a pad of florisil, eluting with ether. The crude aldehyde was used without any further purification.
cis-Butene ( $40 \mathrm{~cm}^{3}$ ) was condensed into a measuring cylinder at $-78^{\circ} \mathrm{C}$ and transferred by cannula into a stirred solution of potassium tert-butoxide $(15.6 \mathrm{~g}, 0.14 \mathrm{~mol})$ in THF $\left(250 \mathrm{~cm}^{3}\right)$ at $-78^{\circ} \mathrm{C}$. $n$-Butyllithium ( 2.5 m in hexanes, $60 \mathrm{~cm}^{3}, 0.14 \mathrm{~mol}$ ) was added dropwise and the mixture was warmed to $-45^{\circ} \mathrm{C}$ for 10 minutes. Stirring was continued for $45 \mathrm{~min}-$ utes, then the mixture was cooled to $-90^{\circ} \mathrm{C}$. Boron trifluoridediethyl ether ( $25 \mathrm{~cm}^{3}, 0.2 \mathrm{~mol}$ ) was added, followed immediately by a pre-cooled $\left(-78^{\circ} \mathrm{C}\right)$ solution of the crude aldehyde in ether $\left(100 \mathrm{~cm}^{3}\right)$. Stirring was continued at $-90^{\circ} \mathrm{C}$ for 16 hours. The reaction mixture was allowed to warm to room temperature, 3 m aqueous sodium hydroxide ( $250 \mathrm{~cm}^{3}$ ) added, then the mixture heated to a gentle reflux before adding $30 \%$ aqueous hydrogen peroxide $\left(80 \mathrm{~cm}^{3}\right)$ dropwise. The resulting mixture was heated under reflux for 5 hours, cooled to room temperature and the organic phase separated and washed with saturated aqueous $\mathrm{Na}_{2} \mathrm{SO}_{3}$. The combined aqueous phases were extracted with ethyl acetate $\left(4 \times 150 \mathrm{~cm}^{3}\right)$ and the combined organic layers were dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and evaporated to dryness. DMSO ( $3.4 \mathrm{~cm}^{3}, 3.75 \mathrm{~g}, 48 \mathrm{mmol}$ ) in dry dichloromethane ( 10 $\mathrm{cm}^{3}$ ) was added dropwise to a stirred solution of oxalyl chloride $\left(12 \mathrm{~cm}^{3}, 24 \mathrm{mmol}, 2.0 \mathrm{~m}\right.$ in dichloromethane) in dry dichloro-
methane $\left(40 \mathrm{~cm}^{3}\right)$ at $-60^{\circ} \mathrm{C}$ under argon. The solution was stirred at $-60^{\circ} \mathrm{C}$ for 10 minutes then a solution of alcohol $\mathbf{2 8}^{5 f}$ ( $6.57 \mathrm{~g}, 20 \mathrm{mmol}$ ) in dry dichloromethane $\left(40 \mathrm{~cm}^{3}\right.$ ) was added dropwise via a cannula. After stirring at $-60^{\circ} \mathrm{C}$ for a further 20 minutes, triethylamine ( $6.7 \mathrm{~cm}^{3}, 4.86 \mathrm{~g}, 48 \mathrm{mmol}$ ) was added and the mixture was allowed to warm to room temperature. The reaction mixture was quenched with excess $1 \% \mathrm{w} / \mathrm{v}$ aqueous $\mathrm{KHSO}_{4}$ and extracted with dichloromethane. The combined extracts were dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ and concentrated in vacuo to give crude (S)-3-[(1,1-dimethylethyl)diphenylsilyloxy]-2-methylpropanal.

Condensed trans-but-2-ene ( $7 \mathrm{~cm}^{3}$ ) was added to a solution of freshly sublimed potassium tert-butoxide ( $2.8 \mathrm{~g}, 25 \mathrm{mmol}$ ) in dry THF $\left(25 \mathrm{~cm}^{3}\right)$ at $-78^{\circ} \mathrm{C}$. $n$-Butyllithium ( $10 \mathrm{~cm}^{3}, 2.5 \mathrm{~m}$ in hexanes, 25 mmol ) was added dropwise at $-78^{\circ} \mathrm{C}$, the solution stirred at $-45^{\circ} \mathrm{C}$ for 10 minutes, recooled to $-78^{\circ} \mathrm{C}$ and a solution of $(-)-B$-methoxydiisopinocamphenylborane $(9.49 \mathrm{~g}, 30 \mathrm{mmol})$ in dry ether ( $30 \mathrm{~cm}^{3}$ ) added. After stirring at $-78{ }^{\circ} \mathrm{C}$ for 45 minutes boron trifluoride-diethyl ether (4.43 $\mathrm{cm}^{3}, 5.11 \mathrm{~g}, 36 \mathrm{mmol}$ ) was added, the mixture cooled to $-85^{\circ} \mathrm{C}$ and a solution of the crude ( $S$ )-3-[(1,1-dimethylethyl)-diphenylsilyloxy]-2-methylpropanal in ether ( $40 \mathrm{~cm}^{3}$ ) was added. The mixture was stirred at $-85^{\circ} \mathrm{C}$ for a further 20 hours, allowed to warm to room temperature and then 3 m aqueous $\mathrm{NaOH}\left(18 \mathrm{~cm}^{3}\right)$ and $30 \%$ aqueous hydrogen peroxide ( $7.5 \mathrm{~cm}^{3}$ ) were added. The reaction mixture was heated at reflux for 1 hour, cooled and carefully quenched with saturated aqueous $\mathrm{Na}_{2} \mathrm{SO}_{3}$. Saturated aqueous NaCl was added and the solution extracted with ether. The combined extracts were dried $\left(\mathrm{MgSO}_{4}\right)$, concentrated in vacuo and dissolved in dry ether (100 $\mathrm{cm}^{3}$ ). Diethanolamine ( $3.2 \mathrm{~cm}^{3}, 3.47 \mathrm{~g}, 33 \mathrm{mmol}$ ) was added to this solution and the mixture stirred for 16 hours under argon. The mixture was filtered and the filtrate concentrated in vacuo. Methanol ( $6.9 \mathrm{~cm}^{3}$ of a 2.0 m solution in THF, 13.8 mmol ) was added to lithium aluminium hydride ( $13.8 \mathrm{~cm}^{3}$ of a 1.0 m solution in THF, 13.8 mmol ) at room temperature. After 5 minutes ( $S$ )-1,1'-binaphth-2-ol ( $S$-BINAL) ( $3.94 \mathrm{~g}, 10 \mathrm{mmol}$ ) was
added dropwise and then stirred for 30 minutes, and cooled to $-100^{\circ} \mathrm{C}$. Enone $39(2.78 \mathrm{~g}, 6.9 \mathrm{mmol})$ in THF ( $13 \mathrm{~cm}^{3}$ ) was added slowly over 10 minutes and the mixture stirred at this temperature for 16 hours. The reaction was quenched by the sequential addition of methanol ( $6.6 \mathrm{~cm}^{3}$ ) followed by water $\left(6.6 \mathrm{~cm}^{3}\right)$. The mixture was warmed to room temperature, then solid sodium hydrogen carbonate added and the mixture stirred for 1 hour and then filtered. The filtrate was poured into ether ( $300 \mathrm{~cm}^{3}$ ) and the organic layer separated. The organics were washed with water and brine, then dried $\left(\mathrm{MgSO}_{4}\right)$, filtered and concentrated in vacuo.
