#### Abstract

The chemoenzymic synthesis is described of $\beta$-D-Gal $p-(1 \rightarrow 4)-\beta$-D-Glc $p-(1 \rightarrow 6)-[\beta-\mathrm{D}-\mathrm{Gal} p-(1 \rightarrow 4)]-\beta-\mathrm{D}-$ Glcp $\mathrm{NAc}-\left(1 \rightarrow \mathrm{O}\left[\mathrm{CH}_{2}\right]_{3} \mathrm{O} \rightarrow 4\right)-\beta$-D-Glc $p-\left(1 \rightarrow \mathrm{OCH}_{2} \mathrm{CH}=\mathrm{CH}_{2}\right) 32$ and $\beta$-D-Gal $p-(1 \rightarrow 4)-\beta$-d-GlcpNAc- $(1 \rightarrow$ $\left.\mathrm{O}\left[\mathrm{CH}_{2}\right]_{3} \mathrm{O} \rightarrow 4\right)-\beta$-D-Glc $p-(1 \rightarrow 6)-[\beta-\mathrm{D}-\mathrm{Galp} p-(1 \rightarrow 4)]-\beta-\mathrm{D}-\mathrm{Glc} p \mathrm{NAc}-\left(1 \rightarrow \mathrm{O}\left[\mathrm{CH}_{2}\right]_{3} \mathrm{O} \rightarrow 4\right)-\beta-\mathrm{D}-\mathrm{Glc} p-\left(1 \rightarrow \mathrm{OCH}_{2}-\right.$ $\mathbf{C H}=\mathrm{CH}_{2}$ ) 33, representing hexa- and octasaccharide mimics of fragments of the Streptococcus pneumoniae type 14 polysaccharide. In a chemical approach the intermediate linear oligosaccharide mimics 30 and 31 were synthesized, wherein both terminal and non-terminal $N$-acetyl- $\beta$-D-glucosamine residues were not yet galactosylated. The alkyl-bridged derivatives were found to be good acceptor substrates for bovine milk $\beta-1,4$-galactosyltransferase. Reaction of the anomeric allyl functions with cysteamine under UVirradiation gave the corresponding 3-(2-aminoethylthio)propyl glycosides 34 and 35, suitable for further coupling of the oligosaccharide mimics to protein carriers.

## Introduction

Pneumococcal infections are major causes of bacterial pneumonia, otitis media and meningitis and despite the availability of antibiotic therapy is still a significant cause of mortality throughout the world. ${ }^{1,2}$ Owing to the rapid course of the disease and the emergence of antibiotic-resistant strains, ${ }^{3-5}$ disease prevention by vaccination is highly desirable. The current polyvalent pneumococcal vaccines Pneumovax $23^{\circledR}$ (Merck, Sharp and Dohme) and Pnu-Immune 23 (Lederle-Praxis), which contain the capsular polysaccharides of 23 of the most common serotypes, ${ }^{6}$ offer $90 \%$ protection in immunocompetent adults, but are inadequate in the population at greatest risk for serious pneumococcal infections. ${ }^{7,8}$ The immune response to T-cell-independent (TI) polysaccharide antigens is poor in infants and young children up to the age of 2 years. The development of more immunogenic conjugate vaccines for serotypes responsible for most pediatric diseases (e.g. 6B, 14, $18 \mathrm{C}, 19 \mathrm{~F}$, and 23 F ) is thus of great importance. ${ }^{9,10}$
The Streptococcus pneumoniae type 14 polysaccharide (Pn 14 -PS) consists of a branched tetrasaccharide repeating unit ${ }^{11}$ which is structurally identical with the asialo core antigen of the type III group B Streptococcus (GBS III) capsular polysaccharide: ${ }^{12}$

\(\rightarrow 6)-\beta\)-d-Glc \(p\) NAc-( \(1 \rightarrow 3\) )- \(\beta\)-d-Galp-( \(1 \rightarrow 4\) )- \(\beta\)-d-Glcp \((1 \rightarrow\)
    4
    \(\uparrow\)
    1
    \(\beta\)-D-Galp
```

Structural similarities between antigenic determinants of the Pn 14 polysaccharide and human oligosaccharide structures, which may give rise to the induction of autoantibodies and suppression of the immune response, may be responsible for the poor immunogenicity of the Pn 14 polysaccharide among the pneumococcal capsular polysaccharides. ${ }^{13}$ Evidence for crossreactivity with human tissue was found by immunization of both rabbits and mice with Pn 14-PS. ${ }^{14}$

As autoreactive antibodies were preferentially reactive with lactose, we designed mimics of the Pn 14 polysaccharide in which the galactose moiety of the repeating $\rightarrow 6$ )- $\beta$-D-Glc $p$ NAc-
$(1 \rightarrow 3)$ - $\beta$-D-Galp-( $1 \rightarrow 4$ )- $\beta$-D-Glcp-( $1 \rightarrow$ trisaccharide backbone structure is substituted by a flexible acyclic spacer. For an easy access to branched-chain oligosaccharide mimics, also the $\beta$-1,4-galactosyltransferase-catalyzed galactosylation of N -acetyl- $\beta$-d-glucosamine residues of linear oligosaccharide mimics, using uridine-5'-diphosphogalactose (UDP-Gal) as donor, was investigated.
Owing to its availability and flexibility both in donor and acceptor substrate specificity, $\beta$-1,4-galactosyltransferase is one of the most extensively studied mammalian glycosyltransferases. ${ }^{15,16}$ Two findings stimulated our approach to branched-chain oligosaccharide mimics by enzymic galactosylation. $\beta$-1,4-Galactosyltransferase (UDP-Gal: D-glucose $\beta-1,4-$ galactosyltransferase [EC 2.4.1.22]), which uses D-glucose as the preferred acceptor in the presence of $\alpha$-lactalbumin, is regarded as transferring in vivo galactose to only terminal $N$-acetyl- $\beta$-d-glucosamine residues. ${ }^{17,18}$ However, 6-O-glycosylated $N$-acetyl- $\beta$-D-glucosamine derivatives like $\alpha$-L-Fucp$(1 \rightarrow 6)-\beta$-d-Glc $p$ NAc, ${ }^{19} \quad \alpha$-Neup $5 \mathrm{Ac}(\mathrm{OMe})-(2 \rightarrow 6)-\beta$-d-Glc $p-$ NAc, ${ }^{19}$ and $\beta$-D-Galp-( $1 \rightarrow 4$ )- $\beta$-D-Glcp-( $1 \rightarrow 6$ )- $\beta$-D-Glc $p$ NAc$(1 \rightarrow \mathrm{OAll})^{20}$ were found to be substrates of the enzyme. Furthermore, a large variety of aglycones are readily tolerated by the enzyme, and even increasing galactosylation has been observed for $N$-acetyl- $\beta$-d-glucosamine glycosides of hydrophobic aglycones. ${ }^{21,22}$ This so called hydrophobic effect was confirmed by studies on recognition- and binding-subsites of the enzyme using diantennary alkyl-bridged oligosaccharides with terminal $N$-acetyl- $\beta$-D-glucosamine residues. ${ }^{23,24}$

Here, we report on the chemoenzymic synthesis of alkylbridged oligosaccharide mimics of fragments of the Streptococcus pneumoniae type 14 polysaccharide containing an aglycone spacer for the subsequent attachment to carrier proteins.

## Results and discussion

The convergent synthetic strategy for the preparation of the key linear oligosaccharide mimic derivatives 18 and 19 involves the glycosylation of the common trisaccharide mimic acceptor 9 with either disaccharide $\mathbf{1 1}$ or trisaccharide mimic $\mathbf{1 7}$ thioethyl glycoside donors. In a series of protecting-group manipulations key compounds $\mathbf{1 8}$ and $\mathbf{1 9}$ can be converted into the

Both the synthesis of the trisaccharide mimic acceptor 9 and donor 17 required the 2-(trimethylsilyl)ethyl (TMSE) 4-O-(3hydroxypropyl) glycoside 4 as intermediate (Scheme 1). For anomeric protection the 2-(trimethylsilyl)ethyl group was chosen, as TMSE glycosides are compatible with a wide range of different reaction conditions as well as being easy removable by reaction with TFA in dichloromethane without affecting the glycosidic bonds. ${ }^{25}$

The $4-O$-alkylated glycoside $\mathbf{3}$ was prepared in $96 \%$ yield by reaction of 2-(trimethylsilyl)ethyl 2,3,6-tri- $O$-benzyl- $\beta$-d-glucopyranoside ${ }^{25} 2$ with 3-(tert-butyldimethylsilyloxy)propyl bromide ${ }^{26} \mathbf{1}$ in a $1: 1$ mixture of DMF and THF. Subsequent removal of the acid-sensitive tert-butyldimethylsilyl (TBDMS) group with $p-\mathrm{TsOH}$ in aq. acetonitrile gave glycosyl acceptor $\mathbf{4}$ in 97\% yield.

For the synthesis of the trisaccharide mimic acceptor 9 a combination of tert-butyldiphenylsilyl (TBDPS) and $p$-methylbenzoyl (MBz) protecting groups was chosen, which had already successfully been used in the preparation of the $\beta$-D-Galp-( $1 \rightarrow 4$ )- $\beta$-D-Glcp- $(1 \rightarrow 6)-\beta$-D-Glcp $N A c-(1 \rightarrow \mathrm{OAll})$ trisaccharide fragment of the $S$. pneumoniae type 14 polysaccharide. ${ }^{20}$ The suitably protected 6 - $O$-silylated $\beta$-thioglycoside

Scheme 2 Reagents and yields: i, NIS, AgOTf (18: 42\%; 19: 66\%).
donor 7 was prepared in $65 \%$ overall yield by deacetylation of ethyl 3,4,6-tri- $O$-acetyl-2-deoxy-2-phthalimido-1-thio- $\beta$-dglucopyranoside ${ }^{27} 5$, followed by selective silylation of the primary HO-6 group with tert-butyldiphenylsilyl chloride (TBDPSCl) $(\longrightarrow \mathbf{6})$ and subsequent $p$-methylbenzoylation of the HO-3 and HO-4 groups with MBzCl. $N$-Iodosuccinimide (NIS) promoted glycosylation of the primary hydroxy group of the 4 - $O$-(3-hydroxypropyl) glycoside 4 with $\beta$-thioethyl glycoside 7 in the presence of a catalytic amount of silver trifluoromethanesulfonate (AgOTf) ${ }^{28,29}$ afforded the desired trisaccharide mimic 8 in $85 \%$ yield. Selective desilylation with acetyl chloride in 1:1 methanol-toluene ${ }^{30}$ gave the desired trisaccharide mimic acceptor 9 in $89 \%$ yield.

As the anomeric TMSE group of glycosyl acceptor $\mathbf{9}$ is not compatible with Lewis acid-induced activation of glycosyl imidates, ${ }^{31}$ the $\beta$-thioethyl group was chosen for anomeric activation of both disaccharide donor 11 and trisaccharide mimic donor 17.

As per-acetylated $\alpha$-lactose, which is formed by acetylation of lactose with acetic anhydride in pyridine, does not form the corresponding thioglycoside upon reaction with ethanethiol in the presence of Lewis acid, ${ }^{32}$ the thiolactoside $\mathbf{1 1}$ was prepared in $94 \%$ yield by reaction of lactosylimidate $\mathbf{1 0}^{33}$ with ethanethiol in the presence of boron trifluoride-diethyl ether.
For the preparation of the trisaccharide mimic donor 17 first the 4-O-(3-hydroxypropyl) glucoside 4 was coupled with glycosyl bromide $\mathbf{1 2}^{34}$ in the presence of AgOTf to give compound 13 in $76 \%$ yield. Hydrogenolytic cleavage of the benzyl groups of compound $\mathbf{1 3}$ with $10 \% \mathrm{Pd}-\mathrm{C}$ as catalyst in acetic acid and subsequent $O$-acetylation with acetic anhydride in pyridine gave hexaacetate $\mathbf{1 4}$ in $84 \%$ overall yield. Then, TMSE glycoside 14 was converted into $\beta$-thioglycoside 17 by selective removal of the anomeric 2-(trimethylsilyl)ethyl group with TFA in dichloromethane ( $\longrightarrow \mathbf{1 5}, 96 \%$ ), followed by imidation with trichloroacetonitrile in the presence of DBU $(\longrightarrow \mathbf{1 6}, 89 \%$ ) and subsequent glycosylation with ethanethiol in the presence of $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}(\longrightarrow \mathbf{1 7}, 87 \%)$.

NIS/AgOTf-promoted reactions of glycosyl acceptor 9 with thioglycosides $\mathbf{1 1}$ and $\mathbf{1 7}$ gave the key $6^{\prime}-O$-glycosylated compounds $18(42 \%)$ and $19(66 \%)$, respectively (Scheme 2$)$.

De- $N$-phthaloylation of intermediates 18 and 19 was achieved in high yield by applying a reaction sequence estab-
lished earlier as a consequence of MBz group migration during de- $N$-phthaloylation. ${ }^{20}$ Thus, compounds 18 and 19 were first de- $O$ - $p$-methylbenzoylated and de- $O$-acetylated with sodium methoxide in methanol, and subsequently de- $N$-phthaloylated with ethylenediamine in butan-l-ol ${ }^{35}$ for 24 h at $80^{\circ} \mathrm{C}$. Re- N,O-acetylation gave compounds 20 ( $95 \%$ ) and 21 ( $97 \%$ ), respectively (Scheme 3). Removal of the benzyl groups by hydrogenolysis with $10 \% \mathrm{Pd}-\mathrm{C}$ as catalyst in acetic acid, followed by $O$-acetylation, gave the per- $O$-acetylated 2-(trimethylsilyl)ethyl glycosides 22 and $\mathbf{2 3}$ in $72 \%$ and $84 \%$ yield, respectively.

In subsequent reactions compounds 22 and 23 were converted into allyl glycosides 26 and 29, respectively, by treatment with TFA in dichloromethane $[\longrightarrow$ hemiacetal sugars 24 ( $90 \%$ ) and $27(84 \%)$ ], followed by imidation with trichloroacetonitrile in the presence of DBU $[\longrightarrow \mathbf{2 5}(85 \%)$ and 28 ( $82 \%)$ ], and subsequent allylation with allyl alcohol and $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}[\longrightarrow \mathbf{2 6}$ ( $61 \%$ ) and $29(59 \%)]$. Deacetylation with sodium methoxide in methanol furnished the linear glycosyl mimics $30(86 \%)$ and 31 ( $92 \%$ ), respectively.

The bovine $\beta$-1,4-galactosyltransferase-catalyzed syntheses of the branched-chain oligosaccharide mimics 32 and 33 was achieved by transfer of galactosyl groups from UDP-galactose to the $N$-acetyl- $\beta$-D-glucosamine residues of intermediates $\mathbf{3 0}$ and 31, respectively (Scheme 4). Initial reaction rates were determined under standard conditions with a coupled enzyme assay for UDP. ${ }^{36}$ With $N$-acetyl-D-glucosamine taken as a reference (with an assigned relative rate of 100 ) the pentasaccharide mimic 30, containing a non-terminal 6-O-substituted N -acetyl-$\beta$-d-glucosamine residue, showed good acceptor activity ( $35 \%$ ). The hexasaccharide mimic 31, containing both terminal and non-terminal $N$-acetyl- $\beta$-D-glucosamine residues, was found to be a weaker acceptor ( $15 \%$ ).

Oligosaccharide mimics $\mathbf{3 2}$ and $\mathbf{3 3}$ were then prepared on a preparative scale. Alkaline phosphatase was added to the incubation mixtures to prevent feedback inhibition by released UDP ${ }^{37,38}$ and to promote a high conversion of the acceptor $[\longrightarrow 32(85 \%)$ and $33(80 \%)]$. Fast-atom bombardment (FAB) mass spectrometry confirmed the introduction of one galactosyl residue in compound 32 and the presence of two galactosyl residues in compound 33 . The ${ }^{13} \mathrm{C}$ NMR spectra of compounds $\mathbf{3 2}$ and $\mathbf{3 3}$ showed the expected

additional anomeric signals, corresponding to mono- (32) and di-galactosylation (33), respectively. Furthermore, 2D COSY,$\dagger$ TOCSY $\dagger$ and ROESY $\dagger$ spectra confirmed the structures of compounds 32 (Table 1) and 33 (Table 2), with interresidual nuclear Overhauser effects (NOEs) between 1-H of the transferred galactose and $4-\mathrm{H}$ of terminal and non-terminal $N$-acetylglucosamine residues, respectively.

The allyl glycosides 32 and 33 were then converted by reaction with cysteamine ${ }^{39}$ under UV-irradiation into the 3-(2aminoethylthio)propyl glycosides 34 and 35 , respectively, suitable for conjugation to carrier proteins.

Conjugation of the type 14 oligosaccharide mimics to $\mathrm{CRM}_{197}$ (cross-reactive material) and immunological studies are in progress.

Bovine milk $\beta$-1,4-galactosyltransferase (EC 2.4.1.22), $\ddagger$ UDPgalactose, $\beta$-nicotinamide adenine dinucleotide (reduced form; $\beta$-NADH), phospho(enol)pyruvate, pyruvate kinase (EC 2.7.1.40, type III from rabbit muscle), $\S$ L-lactic dehydrogenase (EC 1.1.1.27, type XI from rabbit muscle), $\|$ and alkaline phosphatase (EC 3.1.3.1, type I from bovine intestine) \| were obtained from Sigma.

## Measurement of galactosyltransferase activity

Initial reaction rates were determined under standard conditions at $20^{\circ} \mathrm{C}$ in $500 \mu \mathrm{l}$ sodium cacodylate buffer ( $100 \mathrm{~mm}, \mathrm{pH}$ 7.5) containing $10 \mathrm{~mm} \mathrm{MnCl}_{2}, 50 \mathrm{~mm} \mathrm{KCl}, 0.2 \mathrm{~mm}$ UDP-galactose, 1 mm phospho(enol)pyruvate, $0.3 \mathrm{~mm} \beta-\mathrm{NADH}, 25 \mathrm{U}$ pyruvate kinase, 25 U L-lactic dehydrogenase, 10 mm acceptor, and $20 \mathrm{U} \beta$-1,4-galactosyltransferase. Formation of UDP was followed by monitoring the decrease in absorbance at 340 nm .

The allyl glycoside $32(11.1 \mathrm{mg}, 11.5 \mu \mathrm{~mol})$ was dissolved in aq. cysteamine hydrochloride ( $6.6 \mathrm{mg}, 57.5 \mu \mathrm{~mol}$ in $300 \mu \mathrm{l}$ ), and the mixture was irradiated under UV-light for 3 h at rt . The product was purified by size-exclusion chromatography on a Toyopearl HW-40S column, eluted with 0.1 m aq. $\mathrm{NH}_{4} \mathrm{OAc}$ at a flow rate of $13 \mathrm{ml} \mathrm{h}^{-1}$. Product-containing fractions were lyophilized and deionized on a Dowex 1 $\mathrm{X} 8\left(\mathrm{OH}^{-}\right.$-form) column with water as eluent to give title glycoside 34 ( $9.4 \mathrm{mg}, 78 \%$ ); TLC (butan-1-ol-water-HOAc, $2: 1: 1$ ) $R_{\mathrm{f}} 0.17$ (32), 0.08 (34); $\delta_{\mathrm{H}}(300 \mathrm{MHz}$; $\left.\mathrm{CDCl}_{3}\right) 4.57-4.52\left(3 \mathrm{H}, 1^{\prime}-\right.$, $1^{\prime \prime}$ - and $\left.1^{\prime \prime \prime \prime}-\mathrm{H}\right), 4.45$ and 4.43 (each $1 \mathrm{H}, 2 \mathrm{~d}, J 7.4$ and $7.7,1-$ and $\left.1^{\prime \prime \prime}-\mathrm{H}\right), 4.29\left(1 \mathrm{H}, \mathrm{d}, J 10.5,6^{\prime}-\mathrm{H}\right)$, 3.09, 2.80 and 2.69 (each $2 \mathrm{H}, 3 \mathrm{t}, \mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{SCH}_{2}-$ $\mathrm{CH}_{2} \mathrm{NH}_{2}$ ) and $2.05\left(3 \mathrm{H}, \mathrm{s}, \mathrm{NHCOCH}_{3}\right) ; \delta_{\mathrm{C}}\left(75.5 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right)$ $176.2\left(\mathrm{NHCOCH}_{3}\right), 104.6,104.4,104.1,103.9$ and $102.8(\mathrm{C}-1$, $\left.-1^{\prime},-1^{\prime \prime},-1^{\prime \prime \prime},-1^{\prime \prime \prime \prime}\right), 80.1,79.9,79.4,77.2,77.0,76.9,76.8,76.4$, $76.0,75.1,74.9,74.3,74.2,74.0,72.6$ and 70.2 (C-2, $-3,-4$, $-5,-3^{\prime},-4^{\prime},-5^{\prime},-2^{\prime \prime},-3^{\prime \prime},-4^{\prime \prime},-5^{\prime \prime},-2^{\prime \prime \prime},-3^{\prime \prime \prime},-4^{\prime \prime \prime},-5^{\prime \prime \prime},-2^{\prime \prime \prime},-3^{\prime \prime \prime \prime},-4^{\prime \prime \prime \prime}$, $\left.-5^{\prime \prime \prime \prime}\right), 71.3,70.4,69.0,68.6,62.7,62.7,62.2$ and 61.8 (C-6, -6', $-6^{\prime \prime},-6^{\prime \prime \prime},-6^{\prime \prime \prime \prime} \mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{O}$ and $\left.\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{~S}\right), 56.8$ ( $\mathrm{C}-2^{\prime}$ ), 40.4, 31.7, 30.5, 30.4 and $28.8\left(\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{O}\right.$ and $\left.\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{SCH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{2}\right)$ and $23.2 \quad\left(\mathrm{NHCOCH}_{3}\right)$; FABMS of $\mathrm{C}_{40} \mathrm{H}_{72} \mathrm{~N}_{2} \mathrm{O}_{27} \mathrm{~S}(\mathrm{M}, 1044.4) m / z 1045.3(\mathrm{M}+\mathrm{H})^{+}$.
