# Stereocontrol in organic synthesis using silicon-containing compounds. A synthesis of a ( $\pm$ )-carbacyclin analogue with the geometry of the exocyclic double bond controlled by the protodesilylation of an allylsilane 

Ian Fleming* and Dick Higgins<br>Department of Chemistry, Lensfield Road, Cambridge, UK CB2 1EW

#### Abstract

The known ketone, 7-tert-butyldimethylsilyloxybicyclo[3.3.0]oct-8-en-2-one 11, was converted in five steps into 3-(4'-methoxycarbonylbutylidene)-7-tert-butyldimethylsilyloxy-8-cyanobicyclo[3.3.0]octan-2-one 13. Reduction gave the diastereoisomeric pair of allylic alcohols 14 and 15, both of which were converted into the allylsilane, 3-(1'-dimethylphenylsilyl-4'-methoxycarbonyl)butyl-7-tert-butyldimethyl-silyloxy-8-cyanobicyclo[3.3.0]oct-2-ene 20. Protodesilylation of the allylsilane gave a high level of selectivity (>96:4) in favour of the carbacyclin analogue, 5-(4'-methoxycarbonyl)butylidene-3-tert-butyldimethylsilyloxy-2-cyanobicyclo[3.3.0]octane 22, having the exocyclic double bond with the E-configuration.

## Introduction

We and several other groups established that the stereochemistry of electrophilic attack on the double bond of an allylsilane was stereospecifically anti, usually in the sense $\mathbf{1},{ }^{1-4}$ giving an alkene $\mathbf{3}$ with the R group and the A group cis, but with more or less of the reaction taking place from the alternative conformation 2 , creating an alkene $\mathbf{4}$ with the R group and the A group trans (Scheme 1). Most attention has naturally

Scheme 1
been paid to the stereochemistry at the new stereogenic centre, ${ }^{1,2}$ which is opposite in sense in the two products 3 and 4, but it is sometimes possible to use the reaction to control double bond geometry. For example, dihydroxylation using osmium tetroxide, followed by convergent stereospecific elimination, can be made to give either the cis or the trans alkene. ${ }^{3,4}$ Alternatively, stereocontrol might be achieved by arranging for a high proportion of the reaction to take place in conformation 1.
To test this possibility, we investigated the protodesilylation of allylsilanes, creating a double bond exocyclic to a fivemembered ring. ${ }^{5}$ In summary, we found that protodesilylation of the allylsilanes $\mathbf{5}$ took place mainly in the sense $\mathbf{1} \longrightarrow \mathbf{3}$ to give the $E$-alkenes 7 , provided that the group $R$ was moderately large. Similarly, protodesilylation of the allylsilanes $\mathbf{6}$ gave the $Z$-alkenes 8 (Scheme 2). Thus when R was isopropyl, the selectivity for reaction taking place in the sense $\mathbf{1}$ over $\mathbf{2}$ was close to $90: 10$, both for 5 and for $\mathbf{6}$, but when R was a methyl group the degree of selectivity was low and actually reversed in both cases, consistent with our earlier work, ${ }^{2,6}$ and that of Vedejs and

McClure, ${ }^{4}$ and of Curran and Kim, ${ }^{7}$ establishing that electrophilic attack on the double bond of an allylsilane often takes place mainly from conformation 2 when the substituent on the double bond cis to the stereogenic centre is only a hydrogen atom, as here, and when, at the same time, the R group is methyl. A methyl group suffers only a weak $\mathrm{A}^{1,3}$ repulsion with the H atom on the double bond, but an isopropyl group suffers a much larger repulsion. The problem of having a small group like methyl on the stereogenic centre giving mixtures of geometrical isomers in the double bond is not, of course, restricted to allylsilane reactions-it turns up equally with allyl Grignard reactions, where selectivities $(E: Z)$ ranging from 5:1 to $0.2: 1$ have been observed, depending upon the electrophile. ${ }^{8}$

At first sight this limitation does not bode well for our plan to use the protodesilylation of an allylsilane to control the geometry of the exocyclic double bond in a synthesis of a carbacyclin. E-Carbacyclin $\mathbf{9}^{9}$ is a prostacyclin analogue much more potent in inhibiting platelet aggregation than its $Z$-isomer 10. ${ }^{10,11}$ Controlling the geometry of the exocyclic double bond in this molecule is therefore a significant challenge in synthesis, both because the geometry matters, and because it is not obvious how to set it up stereoselectively, given that it is remote from

any resident steric influence. Although a few stereoselective syntheses have appeared, ${ }^{12}$ the original Wittig route gave, as one might expect, both isomers in essentially equal amounts. ${ }^{11,13}$ Our own approach, based on the model reaction $5 \longrightarrow \mathbf{7}$, would seem to be doomed - the methylene chain is likely to be more like a methyl group in its steric effect than an isopropyl, and is therefore unlikely to impart useful levels of stereocontrol Nevertheless, we carried out the synthesis, for we were aware that other factors in our favour would come into play, and so they did. We reported this work in preliminary communications, ${ }^{14}$ and report it in full here.

## Results and discussion

We chose not to deal with the problem of the lower side chain, which is, in any case, the main site of variation in the molecules being tested for clinical usefulness, and assembled instead a cyano analogue. We started from the known, racemic unsaturated ketone $\mathbf{1 1},{ }^{15}$ which was attacked exo on the bicyclic framework by cyanide ion to give the nitrile 12. This addition took place under milder conditions than usual for this conventional procedure, ${ }^{16}$ as befits a bicyclooctenone with a bridgehead double bond. More recent methods for the conjugate addition of cyanide ion, based on trimethylsilyl cyanide in the presence of Lewis acids, ${ }^{17}$ were too harsh, giving elimination products lacking the silyloxy group or even more extensive decomposition. A conventional aldol sequence then gave the ketone 13, with the usual $E$-geometry, but with an unimpressive overall yield, although this was only to be expected from an earlier report on aldol reactions on this type of bicyclooctanone. ${ }^{18}$ We were even less successful with phenylthioalkylation ${ }^{19}$ of the silyl enol ether derived from the ketone 12.

Luche reduction ${ }^{20}$ of the ketone $\mathbf{1 3}$ gave a separable mixture of the alcohols $\mathbf{1 4}$ and $\mathbf{1 5}$ in a ratio of $10: 1$, and acetylation gave the acetates 16 and 17, respectively. The latter, the more important isomer, could also be made by a Mitsunobu reaction from the major alcohol 14 (Scheme 3). Acetic acid is not usually the best carboxylic acid to use in Mitsunobu reactions, ${ }^{21}$ but it worked well enough here.

The acetate $\mathbf{1 6}$ reacted with our silylcuprate reagent, using the solvent mixture that we had found best for secondary allylic acetates, ${ }^{22}$ giving a mixture of the regioisomeric allylsilanes 18 and 19, with the latter, unfortunately, as the minor product, just as we had found earlier in the model series. ${ }^{22}$ In welcome contrast, the acetate $\mathbf{1 7}$ gave only the allylsilane $\mathbf{2 0}$, which was discernibly different from the allylsilane 19 (Scheme 4). By analogy with our earlier work, ${ }^{3}$ these reactions can be relied upon to be stereospecifically anti. Presumably an allylsilane analogous to 18, but with an endo silyl group, was not formed from the acetate 17, because it would have involved endo attack on the bicyclo[3.3.0]octane system. Because of the success of this reaction, we were not obliged to use our other device for ensuring high levels of regioselectivity-the use of a silylcuprate reagent assembled on a carbamate group in place of the acetate. ${ }^{22}$ This was fortunate, for in this case we found that the $N$-phenyl carbamate derived from the alcohol 14 reacted with the silylcuprate reagent, assembled on the carbamate as usual, to give a low yield ( $12 \%$ ) of the allylsilane 19 instead of $\mathbf{2 0}$.

Scheme 3 Reagents: i, $\mathrm{KCN}, \mathrm{NH}_{4} \mathrm{Cl}, \mathrm{H}_{2} \mathrm{O}$, DMF; ii, LDA; iii, $\mathrm{MeO}_{2} \mathrm{C}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{CHO}$; iv, $\mathrm{MeSO}_{2} \mathrm{Cl}, \mathrm{Et}_{3} \mathrm{~N}$; v, DBU ; vi, $\mathrm{NaBH}_{4}, \mathrm{CeCl}_{3}$; vii, $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}$; viii, $\mathrm{AcOH}, \mathrm{EtO}_{2} \mathrm{CN}=\mathrm{NCO}_{2} \mathrm{Et}, \mathrm{Ph}_{3} \mathrm{P}$

Scheme 4 Reagent: i, $\left(\mathrm{PhMe}_{2} \mathrm{Si}_{2} \mathrm{CuLi} \cdot \mathrm{LiCN}, \mathrm{THF}, \mathrm{Et}_{2} \mathrm{O}\right.$, pentane
This appears to be an unprecendented anti $\mathrm{S}_{\mathrm{N}} 2^{\prime}$ reaction of a cuprate, but it is probable that it is a result of a syn 1,3 -shift of the carbamate anion, away from the hindered endo position on the bicyclic framework, followed by an $\mathrm{S}_{\mathrm{N}} 2$ reaction, with the
usual inversion. We did not pursue this problem, since we had by this time found the Mitsunobu alternative for achieving convergence.

Protodesilylation of the allylsilane $\mathbf{1 8}$ merely moved the double bond regioselectively into the ring $\mathbf{2 1}$, as expected, ${ }^{23}$ but the protodesilylations of the two allylsilanes 19 and 20 were not equally stereoselective with respect to the double bond geometry exocyclic to the ring. Protodesilylation of the diastereoisomer 19 gave a mixture of the $E$ - and $Z$-isomers 22 and 23 (Scheme 5) in a ratio of about 2:1, which looked, on the face of

Scheme 5 Reagent: i, $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, 0^{\circ} \mathrm{C}$
it, very much what one might have expected from the model series (Scheme 2) if we assume that a methylene chain is a little more effective than a methyl group in causing the conformation $\mathbf{1}$ rather than $\mathbf{2}$ to be populated. However, the allylsilane $\mathbf{2 0}$ gave very largely ( $>96: 4, \mathrm{GC}$ supported by ${ }^{13} \mathrm{C}$ NMR) the $E$-isomer 22, exactly as we had hoped. The assignment of configuration to the alkenes 22 and $\mathbf{2 3}$ was easy by comparison of the ${ }^{13} \mathrm{C}$ NMR spectra with those reported for the $E$ - and $Z$-isomers of the carbacyclin iloprost. ${ }^{24}$ Although our work with the model compounds would suggest that a methylene chain will not be an effective group in controlling the double bond geometry, we have somehow achieved an extraordinarily high level of control with one of the diastereoisomers but not the other.

The allylsilane 19 that does not give good stereocontrol will probably adopt most readily a conformation close to that shown as 24, with the hydrogen atom eclipsing, or partly eclipsing, the double bond (Scheme 6). Protodesilylation in this conformation will lead to the $E$-isomer 22, but it will involve attack by the proton either syn to the silyl group or endo on the bicyclic system. Since neither of these pathways is likely to be favourable, it is not surprising that this diastereoisomer does not lead cleanly to the $E$-carbacyclin 22. The alternative conformation $\mathbf{2 5}$, which will lead to the $Z$-isomer 23, although probably not

present in as high a concentration, can be protonated in the stereoelectronically favourable sense, that is exo on the bicyclic system and anti to the silyl group. With the allylsilane 20 that does give good stereocontrol, everything is favourable for the formation of the $E$-isomer 22: the more populated conformation 26 is protonated exo on the bicyclic system and anti to the silyl group. The higher-energy conformation 27 of this diastereoisomer, if it were to give any of the $Z$-isomer 23, would have to be protonated either endo on the bicyclic system or syn to the silyl group, and the combination of unfavourable factors effectively suppresses this pathway.

We note finally that the convergent synthesis of the acetate 17, the stereospecific and highly regioselective synthesis of the allylsilane 20, and the highly stereospecific protodesilylation conspire to make the four-step sequence from the enone $\mathbf{1 3}$ to the carbacyclin analogue 22 reasonably efficient ( $50 \%$ ).

## Experimental

Ether refers to diethyl ether.
(5SR,7RS)-7-tert-Butyldimethylsilyloxybicyclo[3.3.0]oct-8-en-2-one 11
1,2-Epoxycyclooct-3-ene, prepared in $89 \%$ yield from cycloocta-1,3-diene ( 160 mmol ) was converted into bicyclo[3.3.0]oct-7-en-2-ol ( $71 \%$ ) using lithium diethylamide, and into the bicyclic ketone using chromic acid. ${ }^{25}$ Treatment with $N$-bromosuccinimide gave the bromohydrin, which was protected as its tertbutyldimethylsilyl ether. $\beta$-Elimination of the bromide using DBU, and chromatography ( $\mathrm{SiO}_{2}$, hexane-EtOAc, 4:1) gave the ketone ( $29 \%$ overall based on the epoxide), which had ${ }^{13} \mathrm{C}$ NMR and IR in agreement with the literature, ${ }^{15} \delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 6.35$ $(1 \mathrm{H}, \mathrm{dd}, J 3$ and $2, \mathrm{HC}=\mathrm{C}), 5.20(1 \mathrm{H}, \mathrm{ddt}, J 8,7$ and $2, \mathrm{HCOSi})$, 3.06-2.98( $1 \mathrm{H}, \mathrm{m}$, bridgehead H$), 2.72(1 \mathrm{H}, \mathrm{dt}, J 8$ and 5 , endo $\mathrm{C} H_{\mathrm{A}} \mathrm{H}_{\mathrm{B}} \mathrm{CO}$ ), 2.53-2.22 ( 3 H , m, exo $\mathrm{CH}_{\mathrm{A}} \mathrm{H}_{\mathrm{B}} \mathrm{CO}$, endo Hs ), 1.65-1.41 ( $2 \mathrm{H}, \mathrm{m}$, exo Hs ), $0.81\left(9 \mathrm{H}, \mathrm{s}, \mathrm{Me}_{3} \mathrm{C}\right)$ and $0.05(6 \mathrm{H}, \mathrm{s}$, $\mathrm{Me}_{2} \mathrm{Si}$ ).

## (1SR,5SR,7RS,8SR)-7-tert-Butyldimethylsilyloxy-8-cyano-

 bicyclo[3.3.0]octan-2-one 12Potassium cyanide ( 26.0 mmol ) was added to a solution of the ketone 11 ( 20.0 mmol ) and ammonium chloride ( 20.0 mmol ) in a mixture of DMF $\left(90 \mathrm{~cm}^{3}\right)$ and water $\left(10 \mathrm{~cm}^{3}\right)$ at $60^{\circ} \mathrm{C}$ and stirred for 4 h . The mixture was diluted with ether and washed with aqueous ammonium chloride and brine. The organic layer was dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated under reduced pressure to give a yellow oil. Chromatography $\left(\mathrm{SiO}_{2}, \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ gave the ketone ( $71 \%$ ); $R_{\mathrm{f}}\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) 0.25 ; v_{\max }(\mathrm{film}) / \mathrm{cm}^{-1} 2240(\mathrm{C} \equiv \mathrm{N})$ and $1740(\mathrm{C}=\mathrm{O}) ; \delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 4.41(1 \mathrm{H}, \mathrm{dt}, J 5$ and $2.5, \mathrm{HCOSi})$, 3.15-3.01 ( $2 \mathrm{H}, \mathrm{m}, \mathrm{HCC} \equiv \mathrm{N}$ and endo $\mathrm{CH}_{\mathrm{A}} \mathrm{H}_{\mathrm{B}} \mathrm{C}=\mathrm{O}$ ), $2.9(1 \mathrm{H}$, dd, $J 9$ and 2, bridgehead $\mathrm{CHC}=\mathrm{O}$ ), 2.49-2.17 $(4 \mathrm{H}, \mathrm{m}$, exo $\mathrm{CH}_{\mathrm{A}} H_{\mathrm{B}} \mathrm{C}=\mathrm{O}$, endo Hs and bridgehead H$), 1.89(1 \mathrm{H}$, dddd, $J 10$, 8,5 and 4, exo $\mathrm{H} \beta$ to $\mathrm{C}=\mathrm{O}$ ), $1.60(1 \mathrm{H}$, ddd, $J 15,2.5$ and 1.5 ,
exo H$), 0.80\left(9 \mathrm{H}, \mathrm{s}, \mathrm{Me}_{3} \mathrm{C}\right)$ and $0.04\left(6 \mathrm{H}, \mathrm{s}, \mathrm{Me}_{2} \mathrm{Si}\right) ; \delta_{\mathrm{C}}\left(\mathrm{CDCl}_{3}\right)$ $216.25(\mathrm{C}=\mathrm{O}), 119.84(\mathrm{C}=\mathrm{N})$, 77.44 (COSi), 54.15, 41.18, 41.56, 37.10, 36.65, $26.57\left(3 \times \mathrm{CH}_{2}, 3 \times \mathrm{CH}\right), 25.44\left(\mathrm{Me}_{3} \mathrm{C}\right), 17.74$ $\left(\mathrm{Me}_{3} C\right),-5.21\left(\mathrm{Si}_{\mathrm{Si}}^{\mathrm{A}} \mathrm{Me}_{\mathrm{B}}\right),-5.26\left(\mathrm{SiMe}_{\mathrm{A}} M e_{\mathrm{B}}\right) ; m / z 264(17 \%$, $\mathrm{M}-\mathrm{Me}$ ), $222\left(100 \%, \mathrm{M}-\mathrm{Bu}^{+}\right)$(Found: $\mathrm{M}^{+}-15,264.1439$. $\mathrm{C}_{14} \mathrm{H}_{22} \mathrm{NO}_{2} \mathrm{Si}$ requires $M, 264.1420$ ). The expected exo configuration of the cyano group was supported by the small coupling constant (2.5) between the proton adjacent to the silyloxy group at $\delta 4.41$ and the proton adjacent to the cyano group.

## Methyl 5-hydroxypentanoate

Sulfuric acid (conc., $0.1 \mathrm{~cm}^{3}$ ) was added to a stirred solution of $\delta$-valerolactone ( 120 mmol ) in methanol $\left(250 \mathrm{~cm}^{3}\right)$ and the mixture refluxed for 4 h . The mixture was cooled to $0{ }^{\circ} \mathrm{C}$ and sodium hydrogen carbonate ( 1.50 g ) added. After the mixture had been stirred for 10 min , it was filtered through Celite and the solvent removed under reduced pressure to give the ester (94\%) identical ( ${ }^{1} \mathrm{H}$ NMR) to that reported. ${ }^{26}$

## Methyl 5-oxopentanoate

The ester ( 80 mmol ) was added to a solution of pyridinium chlorochromate ( 120 mmol ) in dichloromethane $\left(350 \mathrm{~cm}^{3}\right)$ at $0^{\circ} \mathrm{C}$ and allowed to warm to room temperature. The mixture was stirred for 2 h and diluted with ether, filtered through Celite and solvent removed under reduced pressure. The residue was redissolved in ether and the filtration process repeated to remove the remaining chromium residues. The product was purified by column chromatography (hexane-EtOAc, 3:1) to give the aldehyde ( $57 \%$ ), identical (IR and ${ }^{1} \mathrm{H}$ NMR) to the known compound. ${ }^{26}$
( $E$ )(1SR,5SR,7RS,8SR)-3-(4'-Methoxycarbonylbutylidene)-7-tert-butyldimethylsilyloxy-8-cyanobicyclo[3.3.0]octan-2-one 13 LDA ( $1.1 \mathrm{~mol} \mathrm{dm}^{-3}$ in THF, $6.0 \mathrm{~cm}^{3}$ ) was added dropwise to a solution of the ketone $\mathbf{1 2}(6.0 \mathrm{mmol})$ in THF ( $5 \mathrm{~cm}^{3}$ ) under argon at $-78^{\circ} \mathrm{C}$ and stirred for 20 min . Methyl 5 -oxopentanoate $(9.0 \mathrm{mmol})$ was added and the solution stirred for a further 3 min , after which acetic acid ( 6.6 mmol ) was added. The mixture was warmed to room temperature and then diluted with ether, washed with ammonium chloride, dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated under reduced pressure. The residue was dissolved in dichloromethane, triethylamine ( 12.0 mmol ) and methanesulfonyl chloride ( 12.0 mmol ) were added at $0^{\circ} \mathrm{C}$, and the mixture was stirred for 1 h . DBU $(12 \mathrm{mmol})$ was then added and the mixture stirred for a further 1 h , allowing it to warm to room temperature. After dilution with ether, the mixture was washed with aqueous ammonium chloride and brine, dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated under reduced pressure. The residue was chromatographed ( $\mathrm{SiO}_{2}$, EtOAc-hexane, 1:2) to give the ketone ( $25 \%$ ); $R_{\mathrm{f}}$ (EtOAc-hexane, 1:2) $0.41 ; v_{\text {max }}($ film $) / \mathrm{cm}^{-1}$ $2230(\mathrm{C}=\mathrm{N}), 1740(\mathrm{COOMe}), 1720(\mathrm{C}=\mathrm{O})$ and $1650(\mathrm{C}=\mathrm{C})$; $\delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 6.53(1 \mathrm{H}, \mathrm{tt}, J 8$ and $3, \mathrm{HC}=\mathrm{C}), 4.43(1 \mathrm{H}, \mathrm{q}, J 4$, HCOSi), 3.67 ( $3 \mathrm{H}, \mathrm{s}, \mathrm{MeO}$ ), 3.14-2.81 ( $4 \mathrm{H}, \mathrm{m}$, ring Hs) and 2.51-2.29 ( $2 \mathrm{H}, \mathrm{m}$, ring Hs), $2.33\left(2 \mathrm{H}, \mathrm{t}, J 7, \mathrm{CH}_{2} \mathrm{COOMe}\right)$, $2.15\left(2 \mathrm{H}, \mathrm{q}, J 7, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{C}=\mathrm{C}\right), 1.80\left(2 \mathrm{H}\right.$, quintet, $J 7, \mathrm{CH}_{2}{ }^{-}$ $\left.\mathrm{CH}_{2} \mathrm{C}=\mathrm{C}\right), 1.66-1.50(1 \mathrm{H}, \mathrm{m}$, remaining ring H$), 0.77(9 \mathrm{H}, \mathrm{s}$, $\left.\mathrm{Me}_{3} \mathrm{C}\right), 0.02\left(3 \mathrm{H}, \mathrm{s}, \mathrm{Si} M e_{\mathrm{A}} \mathrm{Me}_{\mathrm{B}}\right)$ and $0.01\left(3 \mathrm{H}, \mathrm{s}, \mathrm{SiMe}_{\mathrm{A}} M e_{\mathrm{B}}\right)$; $\delta_{\mathrm{C}}\left(\mathrm{CDCl}_{3}\right) 203.69(\mathrm{C}=\mathrm{O}), 173.45(\mathrm{COOMe}), 137.38(\mathrm{C}=\mathrm{C})$, $136.97(\mathrm{C}=C), 120.18(\mathrm{C} \equiv \mathrm{N}), 77.31(\mathrm{COSi}), 51.58(\mathrm{MeO}), 55.36$, $42.80,42.06,33.65,33.39,32.36,29.02,23.40\left(5 \times \mathrm{CH}_{2}\right.$ $3 \times \mathrm{CH}), 25.37\left(\mathrm{Me}_{3} \mathrm{C}\right), 17.70\left(\mathrm{Me}_{3} \mathrm{C}\right),-5.22\left(\mathrm{Si} M e_{\mathrm{A}} \mathrm{Me}_{\mathrm{B}}\right)$ and $-5.27\left(\mathrm{SiMe}_{\mathrm{A}} M e_{\mathrm{B}}\right) ; m / z 376(13 \%, \mathrm{M}-\mathrm{Me})$ and 334 ( 100, $\mathrm{M}-\mathrm{Bu}^{t}$ ) (Found: $\mathrm{M}^{+}-15,376.1968 . \mathrm{C}_{21} \mathrm{H}_{33} \mathrm{NO}_{4} \mathrm{Si}$ requires $M-15,376.1944)$.
( $E$ )(1SR,2RS,5SR,7RS,8SR)-3-(4'-Methoxycarbonylbutyl-idene)-7-tert-butyldimethylsilyloxy-8-cyanobicyclo[3.3.0]octan-2-ol 14 and ( $E$ )(1SR,2SR,5SR,7RS,8SR)-3-(4'-methoxy-carbonylbutylidene)-7-tert-butyldimethylsilyloxy-8-cyano-bicyclo[3.3.0]octan-2-ol 15
Sodium borohydride ( 1.67 mmol ), cerium(III) chloride ( 1.7
$\mathrm{mmol})$ and the ketone ( 1.5 mmol ) were stirred in methanol ( 2.5 $\mathrm{cm}^{3}$ ) at $0{ }^{\circ} \mathrm{C}$ for 5 min . Aqueous ammonium chloride was added and the mixture extracted with ether. The ether was washed with brine, dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated under reduced pressure.
