#### Abstract

Hydrosilylation of isoprene with chloro(diphenyl)silane gave ( $Z$ )-chloro(2-methylbut-2-enyl)diphenylsilane 7. The cuprate reagent derived from this chloride underwent conjugate addition to methyl cinnamate 11, 1,2-silylcupration with hex-1-yne 16 and allene 18, and allylic displacement reactions with 1-vinylcyclohexyl acetate 20 and ( $Z$ )-1-cyclopentyloct-2-en-1-yl acetate 22 . The silyl group in each of the products was converted into a hydroxy, with the removal of the 2-methylbut-2-enyl group taking place under much milder acidic conditions than those needed to remove the phenyl group from the dimethyl(phenyl)silyl group, and making this group suitable for the conversion of an allylsilane into an allyl alcohol. A stereospecifically anti conjugate displacement of the allylic benzoate group in ( $Z$ )-( $1 S, 5 R, 6 R, 7 R, 1^{\prime} S$ )-7-benzoyloxy-6-( $1^{\prime}$-benzoyloxyoct-2'-enyl)-2-oxabicyclo[3.3.0]octan-3-one 52, and a stereospecifically syn conjugate displacement of the carbamate group in $(Z)-\left(1 S, 5 R, 6 R, 7 R, 1^{\prime} R\right)-7-$ benzoyloxy-6-( $1^{\prime}-N$-phenylcarbamoyloxyoct-2'-enyl)-2-oxabicyclo[3.3.0]octan-3-one 51, gave stereoconvergently the same allylsilane ( $\left.1^{\prime} E, 2^{\prime \prime} Z\right)-\left(1 S, 5 R, 6 R, 7 R, 3^{\prime} S\right)$-7-benzoyloxy-6-[3'-( $2^{\prime \prime}$-methylbut- $2^{\prime \prime}$-enyl)-diphenylsilyloct-1'-enyl]-2-oxabicyclo[3.3.0]octan-3-one 53. Silyl-to-hydroxy conversion gave the allyl alcohol ( $E$ )-( $1 S, 5 R, 6 R, 7 R, 3^{\prime} S$ )-7-benzoyloxy-6-( $3^{\prime}$ 'hydroxyoct-1'-enyl)-2-oxabicyclo[3.3.0]octan-3-one 54 , having the relative and absolute stereochemistry at $\mathrm{C}-15$ of the prostaglandins.

## Introduction

Having developed a method for converting the phenyldimethylsilyl group into a hydroxy with retention of configuration, ${ }^{1}$ and also a stereoselective synthesis of allylsilanes from allylic alcohols, ${ }^{2}$ we were faced with a problem in trying to combine these two methods. We had in mind that we might be able to control the stereochemistry at C-15 in the synthesis of prostaglandin $\mathrm{F}_{2 \alpha} 1$, a long-standing problem, which has excited several solutions. ${ }^{3,4}$ We had the methods for setting up a silyl group [Si] at C-15 with high levels of regio- and stereo-specificity in either sense from either or both of the diastereoisomeric propargyl (prop-2-ynyl) alcohols $\mathbf{3}$ and $\mathbf{4}$ obtained by nucleophilic attack on a C-13 aldehyde 5 (Scheme 1). Our method was not dependent upon any stereoselectivity in the formation of the mixture of propargyl alcohols $\mathbf{3}$ and $\mathbf{4}$. It was only necessary to be able to separate the diastereoisomers, in order to achieve convergence by submitting each to a different protocol, as used already in our synthesis of the Prelog-Djerassi lactone. ${ }^{5}$ However, there was a fundamental problem in the idea when we started the work described in this paper-we could not use our standard phenyldimethylsilyl group as [Si] in the allylsilane 2, because the essential first step in the silyl-to-hydroxy conversion is to remove the phenyl group with an electrophile. Any attempt to attack the phenyl ring would not be able to compete with attack at C-13 of the double bond of the allylsilane. Several silyl groups have been developed to overcome this type of problem, notably Tamao and Ito's diisopropylamino- ${ }^{6}$ and alkoxy-(dimethyl)silyl groups, ${ }^{7}$ Chan's (dimethyl)pyrrolidinomethylsilyl group, ${ }^{8}$ Hayashi and Hiyama's fluoro(diphenyl)silyl group, ${ }^{9}$ Landais' phenylthiocyclopropyl(dimethyl)silyl group ${ }^{10}$ and Roush's ${ }^{11}$ and Kocienski's ${ }^{12}$ various furyl(dimethyl)silyl groups, all of which allow an allylsilane to be converted into an allyl alcohol, but none of which allows the silyl group to be introduced using the powerful silylcuprate chemistry. Taber has solved the problem recently, retaining the phenyldimethylsilyl group, and hence the capacity to use its cuprate - he found that Birch reduction of the phenyl group and treatment with fluoride ion removed it, but he has not actually carried out the

sequence with an allylsilane. ${ }^{13}$ We tried unsuccessfully to remove the phenyl ring of the phenyldimethylsilyl group by converting it into its chromiumtricarbonyl complex-the complex was formed, but the allyl group remained more reactive than the phenyl. ${ }^{14}$ Another solution to the problem has been developed by Tamao and Ito, with their diethylamino(diphenyl)silyl group, which can be made into a cuprate reagent, ${ }^{15}$ while we developed the ( $Z$ )-2-methylbut-2-
enyl(diphenyl)silyl group ${ }^{16}$ and applied it to a prostaglandin synthesis. ${ }^{17}$ We report all our work on this group in full here and in the following paper.

## Results and discussion

The two essential features that we needed were that the silyl group should have a substituent that is attacked by an electrophile more readily than the double bond of the allylsilane $\mathbf{2}$, and that the silyl group should also be capable of being delivered as a cuprate into the organic structure. It was the second requirement that gave us most trouble, for we found that a wide variety of aryldimethylsilyl groups, with aryl groups more susceptible to electrophilic attack than phenyl, could not be prepared as chlorides, ${ }^{18}$ or the chlorides would only give, when they were stirred with lithium, disilanes and not silyllithium reagents. ${ }^{19}$ It appears to be more or less essential to have at least one unsubstituted phenyl group, as Tamao and Ito found with their group, and we found with the group that we eventually succeeded with.

## The ( $Z$ )-2-methylbut-2-enyl(diphenyl)silyl group

The key was provided by a report from Ojima and Kumagai of the regio- and stereo-selective hydrosilylation of isoprene with chloro(dimethyl)silane. ${ }^{20}$ We found, similarly, that hydrosilylation of isoprene using chloro(diphenyl)silane 6 and the same catalyst in a sealed tube gave the silyl chloride 7 with high selectivity and in high yield. Although clean, this silyl chloride proved to be difficult to purify, distillation causing decomposition, but even in its slightly crude state it was easily converted into, successively, the disilane $\mathbf{8}$, the lithium reagent 9 , and the cuprate $\mathbf{1 0}$ (Scheme 2). It appeared to be best not to

isolate the disilane 8 , which could be obtained in $64 \%$ yield, even though its crystallinity gave an opportunity to purify the reagent-once isolated, it needed sonication and powdered lithium to cleave it. It was better to continue stirring the silyl chloride 7 with lithium shot as usual, even though the disilane must have been an intermediate. ${ }^{21}$ An alternative route to the silyl chloride, which does allow some purification by distillation, is described in the following paper.

We tested the cuprate reagent, to make sure that it reacted with each of the substrates that we already knew the phenyldimethylsilylcuprate reacted with, namely $\alpha, \beta$-unsaturated esters $\mathbf{1 1}$ and 14, a terminal acetylene 16, allene $\mathbf{1 8}$ and the allylic acetate 20. The reactions all worked well (Scheme 3), and were suitable for the alkylation and the protonation protocol with the esters $\mathbf{1 1}$ and $\mathbf{1 4}$, giving the diastereoisomeric esters $\mathbf{1 3}$ and $\mathbf{1 5}$, respectively. Moving closer to the prostaglandin problem, the silylcuprate $\mathbf{1 0}$ also reacted with the allylic acetate 22 to give the allylsilane 24 with the substitution pattern of the prostaglandin sidechain, and showing the expected regioselectivity for allylic displacement with an acetate having a cis double bond and the larger substituent at the oxygen-bearing

end of the allylic system. ${ }^{2}$ With a slightly different protocol, assembling the cuprate on the allylic carbamate 23, the reagent gave the same allylsilane 24. The reagent appeared in every way to be similar in its reactivity, regioselectivity and stereoselectivity to the corresponding phenyldimethylsilylcuprate reagent.
We used the ester $\mathbf{1 2}$ to test methods for converting the silyl into a hydroxy group. We had been hopeful that peracid alone, MCPBA, for example, or peracetic acid in acetic acid, would do both jobs at once-the removal of the allyl group by epoxide formation and easy loss of the silyl group, followed immediately by the silyl-to-hydroxy oxidation step. Unfortunately, we were
unable to find conditions that gave anything other than complex mixtures of products. We turned therefore to stepwise methods (Scheme 4). Protodesilylation was easily accomplished

under mild conditions, typically with the boron trifluorideacetic acid complex in dichloromethane (ca. 0.05 m ) at $-10^{\circ} \mathrm{C}$ for five minutes, giving the fluoride 25, or with dilute methanolic hydrochloric acid ( $c a .0 .3 \mathrm{~m}$ ) at room temperature for three hours. In the latter case, the product mixture was about half silanol 26 and half silyl ether 27, even though the proportion of water present must have been only about $4 \%$. We do not know whether this is a kinetic or a thermodynamic result, and comment only that it is known that hydroxide ion is a better nucleophile for silicon than the corresponding alkoxide ion. ${ }^{22}$ The oxidation step could be carried out using Tamao's conditions in the usual way, to give the alcohol 28a. Our one-pot procedure $\mathbf{1 2 \rightarrow 2 8}$ a using bromine, generated in situ in buffered peracetic acid also worked well, as did a one-pot procedure carrying out the protodesilylation with sulfuric acid in methanol, and then basifying the mixture with sodium hydrogen carbonate and adding potassium fluoride and hydrogen peroxide, except that this gave us the acid 28b instead of the ester. The protodesilylation-oxidation sequence applied to the alkylated esters 13, however, did not go to completion under the standard conditions. We isolated the silanol $\mathbf{3 0}$ in comparable amounts to the alcohol 29, indicating that the phenyl groups slow the oxidation down marginally. Increasing the time for the oxidation of the diastereoisomeric ester $\mathbf{1 5}$ from one day to three, and topping up the hydrogen peroxide each day, gave almost complete conversion to the alcohol 31, but we still isolated a small amount of the silanol 32. No doubt this could be remedied by even longer or stronger treatment with the oxidising agent.

We then tested the protodesilylation and oxidation conditions, in various combinations on the other allylsilanes (Scheme 5). Protodesilylations of the allylsilanes $\mathbf{1 7 , 2 1}$ and 24 in meth-

anol gave the silanols 33a, 35a and 37a, and the silyl ethers 33b, 35b and 37b. Protodesilylation of the allylsilane 21 with the boron trifluoride-acetic acid complex gave the silyl fluoride $\mathbf{3 5 c}$. One- or two-pot oxidations gave hexanal, as its 2,4 -dinitrophenylhydrazone 34, and, most significantly, the allylic alcohols 36 and 38. For the last of these, we also found new, essentially neutral conditions, with a combination of potassium bromide in hydrogen peroxide to create the electrophilic brominating agent, and potassium fluoride and hydrogen peroxide to carry out the oxidation step.

## The prostaglandin C-15 problem

With all the exploratory work in hand, we turned to the main task: to synthesise an allylsilane of the type $\mathbf{2}$ from an aldehyde 5. We chose the aldehyde $\mathbf{4 0}$ to be the aldehyde 5 that we would actually use. The protecting groups, both for the C-9 and the $\mathrm{C}-11$ hydroxy groups were esters, limiting us to protocols using cis double bonds derived from the triple bond. Our earlier method, used in the syntheses of the Prelog-Djerassi lactone and of dihydronepetalactone, and which we shall not be able to apply here, required that we reduce the triple bond of one diastereoisomer to a trans double bond using lithium aluminium hydride, and the ester and lactone groups would not be compatible with this protocol. However, we had by this time developed protocols for convergence using a stereospecifically syn displacement for one diastereoisomer and a stereospecifically anti displacement for the other, with a cis double bond in each, avoiding the need for lithium aluminium hydride.

We prepared the aldehyde 40 in essentially quantitative yield from the alcohol 39, already known from the work of Uskokovic ${ }^{23}$ and Kovâcs. ${ }^{24}$ The aldehyde was, not surprisingly,
exceptionally susceptible to elimination of the $\beta$-benzoate group, so that the oxidation was rather dependent upon the virtues of the Dess-Martin periodinane. We also found that the addition of the acetylenic nucleophile gave less of the elimination product when the cerium reagent was used, and, as expected, the addition was only slightly stereoselective, giving the pair of diastereoisomers 41 and 42, which we were not able to separate, in a ratio of $63: 37$ (Scheme 6). Thus the elegantly

Scheme 6 Reagents: i, Dess-Martin; ii, $\mathrm{C}_{5} \mathrm{H}_{13} \mathrm{C}_{\mathrm{E}} \mathrm{CCeCl}_{2}$; iii, $\mathrm{H}_{2}, \mathrm{Pd}$, $\mathrm{MnCl}_{2}$, quinoline, MeOH ; iv, $\mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{MeOH}$
short method in which allylic acetates are transposed in a transition metal-catalysed suprafacial 1,3 shift would not have been easy to apply here, since, like our own earlier method, it requires different double bond geometries with which to achieve convergence. ${ }^{4}$ Fortunately, we were no longer obliged to separate the propargylic alcohols-we could delay the separation until we had the cis-allylic alcohols. Lindlar reduction gave the pair of alcohols 43 and 44, which we were able to separate, and to which we were able to assign structures by converting the minor alcohol 44 into the known alcohol $46,{ }^{4}$ and the mixture of the two alcohols 43 and 44 into a mixture of the alcohols 45 and 46.

From each of the allylic alcohols 43 and 44, we prepared the carbamates $\mathbf{4 8}$ and 51 and the benzoates $\mathbf{4 7}$ and 52 (Schemes 7 and 8 ). The benzoate 47 and the carbamate 48 gave the same allylsilane 49 (Scheme 7) when subjected to our standard protocols. The yield was rather low ( $23 \%$ ) with the three-step procedure assembling the cuprate on the carbamate 48, converting it into the allylsilane 49 , but the two procedures gave us

enough material to carry out the silyl-to-hydroxy conversion into the known 'unnatural' prostaglandin precursor 50. The carbamate 51 and the benzoate 52 gave the diastereoisomeric allylsilane 53 (Scheme 8), for which we found a slightly different protocol for the conversion of the carbamate $\mathbf{5 1}$ into the allylsilane 53: addition of the lithium salt of the carbamate to the $1: 1$ silylcopper reagent gave a $53 \%$ yield, with $29 \%$ of recovered carbamate, which represents a $77 \%$ yield overall. Silyl-to-hydroxy conversion gave the known 'natural' alcohol 54, completing our long held ambition to control the stereochemistry of an allylic alcohol by taking advantage of the versatility of our convergent stereocontrolled methods for setting up allylsilanes.

## Chlorodiphenylsilane 6

Method 1. ${ }^{25}$ Diphenylsilane ( $4.4 \mathrm{~cm}^{3}, 23.7 \mathrm{mmol}$ ) and chlorotriphenylmethane $(6.97 \mathrm{~g}, 25.0 \mathrm{mmol})$ were refluxed in dry benzene ( $100 \mathrm{~cm}^{3}$ ) for 24 h under argon. The mixture was cooled, filtered quickly and the residue washed with cold dry pentane.

Scheme 8 Reagents: i, $\mathrm{PhNCO}, \mathrm{Et}_{3} \mathrm{~N}$; ii, $\mathrm{PhCOCl}, \mathrm{Et}_{3} \mathrm{~N}, \mathrm{DMAP}$; iii, BuLi; iv, $\mathrm{C}_{5} \mathrm{H}_{9} \mathrm{Ph}_{2} \mathrm{SiCu}$; v, 10; vi, $\mathrm{BF}_{3} \cdot 2 \mathrm{AcOH}$; vii, $\mathrm{H}_{2} \mathrm{O}_{2}, \mathrm{KF}, \mathrm{MeOH}$

The organic layers were combined and concentrated under reduced pressure. Kugelrohr distillation of the residue ( 2 distillations were necessary, $150^{\circ} \mathrm{C}$ at 7 mmHg ) (lit., ${ }^{25} 143^{\circ} \mathrm{C}$ at 10 $\mathrm{mmHg})$ gave the chlorosilane ${ }^{25}(4.55 \mathrm{~g}, 88 \%), v_{\max }($ film $) / \mathrm{cm}^{-1}$ $2140(\mathrm{Si}-\mathrm{H}), 1580(\mathrm{Ph})$ and $1120(\mathrm{Si}-\mathrm{Ph}) ; \delta_{\mathrm{H}}\left(250 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right)$ $7.82\left(4 \mathrm{H}, \mathrm{br} \mathrm{d}, J 7.5, o-\mathrm{SiPh}_{2}\right), 7.67-7.47(6 \mathrm{H}, \mathrm{m}, m$ - and $\left.p-\mathrm{SiPh}_{2}\right)$ and $5.91(1 \mathrm{H}, \mathrm{s}, \mathrm{SiH})$.
Method 2. ${ }^{26}$ Diphenylsilane ( $14.1 \mathrm{~cm}^{3}, 76.1 \mathrm{mmol}$ ) was stirred with a suspension of copper(II) chloride ( $20.2 \mathrm{~g}, 150 \mathrm{mmol}$, dried at $120^{\circ} \mathrm{C}$ under vacuum) and copper( I ) iodide ( $0.3 \mathrm{~g}, 1.6$ mmol ) in dry ether ( $250 \mathrm{~cm}^{3}$ ) under nitrogen at room temperature for 4 d , filtered and concentrated under reduced pressure. Distillation of the residue gave the chlorosilane ${ }^{25}(9.5 \mathrm{~g}, 57 \%)$, bp $95-96{ }^{\circ} \mathrm{C}$ at 0.5 mmHg ; identical (IR, ${ }^{1} \mathrm{H}$ NMR) with the earlier sample. This method, although lower yielding, was the easier, and gave a cleaner product.

## ( $Z$ )-Chloro(2-methylbut-2-enyl)diphenylsilane 7

Chlorodiphenylsilane $6(6.58 \mathrm{~g}, 30 \mathrm{mmol})$, freshly distilled isoprene ( $2.18 \mathrm{~g}, 32 \mathrm{mmol}$ ), triphenylphosphine $(0.04 \mathrm{~g}, 0.15$ mmol ) and bis(benzonitrile)palladium dichloride $(0.025 \mathrm{~g}$, 0.065 mmol ) were heated in a sealed tube under argon at $70^{\circ} \mathrm{C}$ for 7 h . The excess isoprene was evaporated off under reduced
pressure to give the chlorosilane ( $8.1 \mathrm{~g}, 94 \%$ ), which was used without further purification; $v_{\max }($ film $) / \mathrm{cm}^{-1} 1660(\mathrm{C}=\mathrm{C}), 1600$ $(\mathrm{Ph})$ and $1120(\mathrm{Si}-\mathrm{Ph}) ; \delta_{\mathrm{H}}\left(250 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right) 7.70(4 \mathrm{H}$, br d, $\left.J 7.5, o-\mathrm{SiPh}_{2}\right), 7.52-7.42\left(6 \mathrm{H}, \mathrm{m}, m\right.$ - and $\left.p-\mathrm{SiPh}_{2}\right), 5.24(1 \mathrm{H}, \mathrm{br}$ q, $J 6.7, \mathrm{CHMe}), 2.39\left(2 \mathrm{H}, \mathrm{s}, \mathrm{SiCH}_{2}\right), 1.63(3 \mathrm{H}, \mathrm{t}, J 1.4$, $M e \mathrm{C}=\mathrm{CH})$ and $1.40(3 \mathrm{H}, \mathrm{d}, J 6.6, \mathrm{CHMe}) ; \delta_{\mathrm{C}}\left(63 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right)$ 134.6, 133.9, 130.7, 130.3, 128.2, 119.8, 26.3, 23.1 and 14.2; $m / z 288\left[19 \%, \mathrm{M}^{+}\left({ }^{37} \mathrm{Cl}\right)\right], 286\left[49, \mathrm{M}^{+}\left({ }^{35} \mathrm{Cl}\right)\right]$ and $77(12, \mathrm{Ph})$ (Found: C, $71.3 ; \mathrm{H}, 6.5 ; \mathrm{Cl}, 12.5 \% ; \mathrm{M}^{+}, 286.0943$ and 288.0912. $\mathrm{C}_{17} \mathrm{H}_{19} \mathrm{SiCl}$ requires $\mathrm{C}, 71.2 ; \mathrm{H}, 6.7 ; \mathrm{Cl}, 12.4 \% ; \mathrm{C}_{17} \mathrm{H}_{19} \mathrm{Si}^{35} \mathrm{Cl}$ requires $M, 286.0945$ and $\mathrm{C}_{17} \mathrm{H}_{19} \mathrm{Si}^{37} \mathrm{Cl}$ requires $M, 288.0915$ ).

## ( $Z$ )-(2-Methylbut-2-enyl)diphenylsilyllithium 9

Method 1. ( $Z$ )-Chloro(2-methylbut-2-enyl)diphenylsilane ( $0.745 \mathrm{~g}, 0.5 \mathrm{~cm}^{3}, 2.6 \mathrm{mmol}$ ) was stirred vigorously for 2 h with lithium shot $(0.068 \mathrm{~g}, 9.8 \mathrm{mmol})$ in dry THF $\left(5 \mathrm{~cm}^{3}\right)$ at $0^{\circ} \mathrm{C}$ under argon. The deep red solution was stored overnight in a freezer at $-18{ }^{\circ} \mathrm{C}$ and used within a few days. The molarity was determined by the double titration method of Gilman as modified by Whitesides. ${ }^{21}$

Method 2. A mixture of the disilane $8(0.88 \mathrm{~g}, 1.75 \mathrm{mmol})$ and lithium powder ( $0.04 \mathrm{~g}, 6 \mathrm{mmol}$ ) in dry THF ( $5 \mathrm{~cm}^{3}$ ) was sonicated for 2 h at $0^{\circ} \mathrm{C}$ under argon. The resulting deep red solution of silyllithium reagent was then stored overnight in a freezer at $-18{ }^{\circ} \mathrm{C}$. Double titration indicated almost quantitative conversion.
( $Z, Z$ )-1,2-Bis(2-methylbut-2-enyl)-1,1,2,2-tetraphenyldisilane 8 Freshly prepared silyllithium reagent $9(0.74 \mathrm{mmol})$ was added dropwise to a stirred solution of the chlorosilane $7(0.289 \mathrm{~g}$, $1.01 \mathrm{mmol})$ in dry THF $\left(5 \mathrm{~cm}^{3}\right)$ at $0{ }^{\circ} \mathrm{C}$ under argon. After stirring at this temperature for 4 h the reaction was quenched with water $\left(10 \mathrm{~cm}^{3}\right)$ and the mixture filtered through Celite and extracted with light petroleum ( $3 \times 10 \mathrm{~cm}^{3}$ ). The organic layers were combined, washed with brine $\left(10 \mathrm{~cm}^{3}\right)$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated under reduced pressure. ## Methyl 3-hydroxy-3-phenylpropanoate 28a

Method 1. Boron trifluoride-acetic acid complex $\left(0.04 \mathrm{~cm}^{3}\right.$, 0.16 mmol ) was added dropwise to a stirred solution of the allylsilane $12(0.051 \mathrm{~g}, 0.12 \mathrm{mmol})$ in dichloromethane $\left(5 \mathrm{~cm}^{3}\right)$ at room temperature under argon. After 30 seconds the mixture was quenched with sodium hydrogen carbonate $(0.175 \mathrm{~g}, 2.1$ mmol ) and the solvent evaporated under reduced pressure. THF ( $4 \mathrm{~cm}^{3}$ ), methanol ( $4 \mathrm{~cm}^{3}$ ), potassium fluoride ( $0.03 \mathrm{~g}, 0.5$ mmol ) and hydrogen peroxide $\left(30 \%, 1 \mathrm{~cm}^{3}, 8.7 \mathrm{mmol}\right)$ were added and the mixture was stirred for 3 d at room temperature, with further hydrogen peroxide $\left(30 \%, 1 \mathrm{~cm}^{3}\right)$ added each day. The mixture was poured into water and extracted with dichloromethane $\left(5 \times 10 \mathrm{~cm}^{3}\right)$. The organic layers were combined, washed with brine $\left(5 \mathrm{~cm}^{3}\right)$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated under reduced pressure. The residue was chromatographed ( $\mathrm{SiO}_{2}, \mathrm{EtOAc}$-hexane, $1: 4$ ) to give the alcohol ${ }^{30}(0.017 \mathrm{~g}, 77 \%)$; $R_{\mathrm{f}}($ EtOAc-hexane, $1: 4) 0.17 ; v_{\max }\left(\mathrm{CDCl}_{3}\right) / \mathrm{cm}^{-1} 3601(\mathrm{OH})$, $3510(\mathrm{br} \mathrm{OH}), 1726(\mathrm{C}=\mathrm{O})$ and $1605(\mathrm{Ph}) ; \delta_{\mathrm{H}}\left(250 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right)$ 7.37-7.25 ( $5 \mathrm{H}, \mathrm{m}, \mathrm{Ph}), 5.14(1 \mathrm{H}$, ddd, $J 8.0,4.3$ and 3.5 , $\mathrm{CHOH}), 3.72(3 \mathrm{H}, \mathrm{s}, \mathrm{OMe}), 3.23(1 \mathrm{H}, \mathrm{d}, J 3.4, \mathrm{OH}), 2.76(1 \mathrm{H}$, dd, $J 16.4$ and $\left.8.4, \mathrm{CH}_{\mathrm{A}} \mathrm{H}_{\mathrm{B}} \mathrm{CO}\right)$ and $2.72(1 \mathrm{H}, \mathrm{dd}, J 16.4$ and $4.5, \mathrm{CH}_{\mathrm{A}} H_{\mathrm{B}} \mathrm{CO}$ ).

Method 2. Peracetic acid ( $36-40 \%$ in $\mathrm{AcOH}, 0.7 \mathrm{~cm}^{3}, 3.5$ mmol ) was added dropwise to a stirred mixture of the allylsilane $12(0.287 \mathrm{~g}, 0.69 \mathrm{mmol})$, potassium bromide $(0.099 \mathrm{~g}$, $0.83 \mathrm{mmol})$ and sodium acetate $(0.17 \mathrm{~g}, 2 \mathrm{mmol})$ in acetic acid $\left(3.5 \mathrm{~cm}^{3}\right)$ at $0^{\circ} \mathrm{C}$. The mixture was allowed to warm to room temperature and more peracetic acid ( $2.1 \mathrm{~cm}^{3}, 10.5 \mathrm{mmol}$ ) and sodium acetate $(0.5 \mathrm{~g}, 6 \mathrm{mmol})$ were added and the mixture stirred overnight. The mixture was quenched with aqueous sodium thiosulfate solution ( $25 \%$ ), the aqueous layer saturated with salt and the mixture extracted with ethyl acetate ( $5 \times 10$ $\mathrm{cm}^{3}$ ). The combined organic layers were washed with saturated aqueous sodium hydrogen carbonate $\left(5 \mathrm{~cm}^{3}\right)$ and brine $\left(5 \mathrm{~cm}^{3}\right)$, dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ and concentrated under reduced pressure. The residue was chromatographed $\left(\mathrm{SiO}_{2}, \mathrm{EtOAc}\right.$-hexane, $\left.1: 4\right)$ to give the alcohol ( $0.099 \mathrm{~g}, 80 \%$ ), identical (TLC, ${ }^{1} \mathrm{H}$ NMR) with the earlier sample.

## Fluoro(2-cyclohexylideneethyl)diphenylsilane 35c

Boron trifluoride-acetic acid complex $\left(0.04 \mathrm{~cm}^{3}, 0.16 \mathrm{mmol}\right)$ was added dropwise to a stirred solution of the allylsilane 21 $(0.058 \mathrm{~g}, 0.16 \mathrm{mmol})$ in dichloromethane $\left(5 \mathrm{~cm}^{3}\right)$ at $-10^{\circ} \mathrm{C}$ under argon. After 5 min the reaction was quenched with sodium hydrogen carbonate ( $0.17 \mathrm{~g}, 2.0 \mathrm{mmol}$ ) and the mixture washed with water $\left(5 \mathrm{~cm}^{3}\right)$ and extracted with dichloromethane $\left(2 \times 15 \mathrm{~cm}^{3}\right)$. The organic layers were combined, washed with brine $\left(5 \mathrm{~cm}^{3}\right)$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated under reduced pressure to give the crude fluorosilane ( $0.050 \mathrm{~g}, 100 \%$ ); $R_{\mathrm{f}}$ (EtOAc-hexane, 1:4) 0.46; $\delta_{\mathrm{H}}\left(250 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right) 7.78-7.60$ $\left(4 \mathrm{H}, \mathrm{m}, o-\mathrm{SiPh}_{2}\right), 7.59-7.25\left(6 \mathrm{H}, \mathrm{m}, m\right.$ - and $\left.p-\mathrm{SiPh}_{2}\right), 5.17(1 \mathrm{H}$, $\mathrm{t}, J 8.2, \mathrm{C}=\mathrm{CH}), 2.36-2.03\left(6 \mathrm{H}, \mathrm{m}, 3 \times \mathrm{CH}_{2} \mathrm{C}=\mathrm{C}\right)$ and $1.75-1.19$ [ $\left.6 \mathrm{H}, \mathrm{m},\left(\mathrm{CH}_{2}\right)_{3} \mathrm{CH}_{2} \mathrm{C}=\mathrm{C}\right]$.

## 2-Cyclohexylideneethanol 36

Method 1. Hydrochloric acid ( $10 \mathrm{~mol} \mathrm{dm}{ }^{-3}, 9$ drops) was stirred with the allylsilane $21(0.104 \mathrm{~g}, 0.28 \mathrm{mmol})$ in a THFmethanol mixture $\left(1: 1,8 \mathrm{~cm}^{3}\right)$ at room temperature for 3 h . The reaction was quenched with sodium hydrogen carbonate ( 0.350 $\mathrm{g}, 4.2 \mathrm{mmol})$. Potassium fluoride ( $0.060 \mathrm{~g}, 1.0 \mathrm{mmol}$ ) and hydrogen peroxide ( $30 \%$, $1 \mathrm{~cm}^{3}, 8.7 \mathrm{mmol}$ ) were added and the mixture was refluxed for 3 h . The mixture was poured into water $\left(5 \mathrm{~cm}^{3}\right)$ and extracted with dichloromethane $\left(5 \times 10 \mathrm{~cm}^{3}\right)$. The organic layers were combined, washed with brine $\left(5 \mathrm{~cm}^{3}\right)$, dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated under reduced pressure. The residue was chromatographed $\left(\mathrm{SiO}_{2}, \mathrm{EtOAc}\right.$-hexane, $\left.1: 4\right)$ to give the alcohol ${ }^{33}(0.022 \mathrm{~g}, 60 \%) ; R_{\mathrm{f}}$ (EtOAc-hexane, 1:4) 0.27 ; $v_{\max }\left(\mathrm{CDCl}_{3}\right) / \mathrm{cm}^{-1} 3330(\mathrm{br} \mathrm{OH})$ and $1667(\mathrm{C}=\mathrm{C}) ; \delta_{\mathrm{H}}(250 \mathrm{MHz}$; $\left.\mathrm{CDCl}_{3}\right) 5.34(1 \mathrm{H}, \mathrm{brt}, J 7.1, \mathrm{C}=\mathrm{CH}), 4.12(2 \mathrm{H}, \mathrm{d}, J 7.1$, $\left.\mathrm{CH}_{2} \mathrm{O}\right), 2.17\left[2 \mathrm{H}, \mathrm{br} \mathrm{s},\left(\mathrm{CH}_{2}\right)_{\mathrm{A}}\left(\mathrm{CH}_{2}\right)_{\mathrm{B}} \mathrm{C}=\mathrm{C}\right], 2.09[2 \mathrm{H}, \mathrm{br} \mathrm{s}$, $\left.\left(\mathrm{CH}_{2}\right)_{\mathrm{A}}\left(\mathrm{CH}_{2}\right)_{\mathrm{B}} \mathrm{C}=\mathrm{C}\right], 1.54\left[6 \mathrm{H}\right.$, br s, $\left.\left(\mathrm{CH}_{2}\right)_{3} \mathrm{CH}_{2} \mathrm{C}=\mathrm{C}\right]$ and 1.23 ( $1 \mathrm{H}, \mathrm{v}$ br s, OH ).

Method 2. The allylsilane $21(0.18 \mathrm{~g}, 0.5 \mathrm{mmol})$, sodium hydrogen carbonate ( $0.25 \mathrm{~g}, 3 \mathrm{mmol}$ ), potassium fluoride ( 0.058 $\mathrm{g}, 1 \mathrm{mmol}$ ), potassium bromide ( $0.12 \mathrm{~g}, 1 \mathrm{mmol}$ ) and hydrogen peroxide ( $30 \%, 2 \mathrm{~cm}^{3}, 17.4 \mathrm{mmol}$ ) were refluxed in a THFmethanol mixture ( $1: 1,10 \mathrm{~cm}^{3}$ ) overnight. Water $\left(5 \mathrm{~cm}^{3}\right)$ was added and the mixture extracted with ethyl acetate $\left(2 \times 20 \mathrm{~cm}^{3}\right)$. The combined organic layers were washed with brine $\left(5 \mathrm{~cm}^{3}\right)$, dried $\left(\mathrm{MgSO}_{4}\right)$ and evaporated under reduced pressure. The residue was chromatographed $\left(\mathrm{SiO}_{2}, \mathrm{EtOAc}\right.$-hexane, $\left.1: 4\right)$ to give the alcohol ( $0.037 \mathrm{~g}, 59 \%$ ) identical (TLC, ${ }^{1} \mathrm{H}$ NMR) with the earlier sample.
