#### Abstract

4-Nitrobenzyl carbamates are of interest as triggers for bioreductive drugs, particularly in conjunction with the E. coli B nitroreductase, which efficiently reduces them to the corresponding hydroxylamines. These then fragment to release highly toxic amine-based toxins. While many 4-nitrobenzyl carbamate derivatives have been evaluated as bioreductive drugs, there has been no systematic study of substituent effects on the rate of this fragmentation (which should be as fast as possible following reduction). We therefore prepared a series of 2-, 3- and $\alpha$-substituted 4-[ $N$-methyl- $N$-(4-nitrobenzyloxycarbonyl)amino]phenylacetamides as model compounds to study these effects. The majority of the carbamates were prepared by in situ formation of the chloroformate of the appropriate 4-nitrobenzyl alcohol and reaction with methyl 4-(methylamino) phenylacetate, followed by ester hydrolysis and 1,1'-carbonyldiimidazole (CDI) mediated coupling with $N, N$-dimethylaminoethylamine. The hydroxylamines were generated by ${ }^{60} \mathrm{Co} \gamma$-ray irradiation of the nitro compounds in aqueous phosphate-buffered-propan-2-ol. The reactions were analysed by reverse-phase HPLC to determine the maximum half-life ( $\mathrm{M} t_{1 / 2}$ ) of the hydroxylamines generated, and the extent of release of amine from these after 10 half-lives $\left(t_{\infty}\right)$. The parent (unsubstituted) hydroxylaminobenzyl carbamate had a $\mathrm{M} t_{1 / 2}$ of 16 min under these conditions, while that of the corresponding $\alpha$-methyl analogue was 9.5 min . Electron-donating substituents on the benzyl ring also accelerated fragmentation, with the data being fitted to the equation $\log \left(\mathrm{M} t_{1 / 2}\right)=0.57 \sigma+1.30$, where $\sigma$ represents $\sigma_{p}$ for 2 -substituents and $\sigma_{m}$ for 3 -substituents. The acceleration of fragmentation of the hydroxylamines with increasing substituent electron-donation is consistent with the proposed mechanism, and is presumably due to stabilisation of the developing positive charge on the benzylic carbon. The extent of release of amine $\left(t_{\infty}\right)$ also increased with increasing substituent electron-donation. These data suggest that the standard 4-nitrobenzyl carbamate trigger for nitroreductase enzyme (NTR) prodrugs can likely be improved on, by increasing the rate of fragmentation by the use of $\alpha$-methyl and/or electron-donating benzyl substituents.

## Introduction

Nitrobenzyl carbamates are of interest as potential bioreductive drugs, because of their ability to undergo fragmentation following reduction. In contrast to the reduction of nitrobenzyl halides ${ }^{1}$ or quaternary salts, ${ }^{2}$ which fragment at the radical anion stage following one-electron reduction, ${ }^{3}$ nitrobenzyl carbamates undergo multi-electron reduction to electron-donating hydroxylamine or amine species, which then fragment to generate a quinomethane imine and an amine. ${ }^{4}$ Initial interest centred around the reduction of compounds such as $\mathbf{1}(\mathrm{R}=\mathrm{Me}$, $\mathrm{Ph})$ by cellular nitroreductases, with the quinomethane or quinonimine species considered to be the potentially cytotoxic agent. ${ }^{5}$ A subsequent study ${ }^{6}$ considered the nitrobenzyl carbamates of 5 -fluorouracil $\mathbf{1}(\mathrm{R}=5-\mathrm{FU})$ as bioreductive agents. However, the reduction potentials of compounds such as $\mathbf{1}$ are too low for efficient reduction by cellular nitroreductases, and the quinonimines generated were not particularly cytotoxic.

Renewed interest in nitrobenzyl carbamates as bioreductive drugs was generated by the discovery of an E. coli B nitroreductase enzyme (NTR) ${ }^{7}$ which, in conjunction with NADH or NADPH, reduces certain aromatic nitro groups to the corresponding hydroxylamines. ${ }^{8}$ Despite the low reduction potentials of typical 4-nitrobenzyl carbamates (ca. -490 mV ), ${ }^{9}$ they undergo reduction by the NTR enzyme (although with widely varying degrees of activation) to the corresponding unstable hydroxylamines. The latter, through increased electron release to the $\pi$-system stabilizing the developing positive charge on the

benzylic carbon, readily fragment to release amines (Scheme 1). The 4-nitrobenzyl carbamate moiety has thus been proposed as a prodrug "trigger" that may deactivate highly cytotoxic amine "effectors" ${ }^{10}$

The $E$. coli enzyme has been used to activate such nitrobenzyl carbamate prodrugs in antibody- ${ }^{11,12}$ and gene-directed enzyme prodrug therapy ${ }^{13}$ (ADEPT and GDEPT, respectively) protocols. Several studies have shown that 4-nitrobenzyl carbamate derivatives of actinomycin, ${ }^{11}$ mitomycin, ${ }^{11}$ enediynes, ${ }^{14}$ amino-seco-cyclopropylindoline derivatives, ${ }^{15}$ and tallimustine derivatives ${ }^{16}$ are substrates for E. coli NTR. The selectivity of the NTR enzyme for the 4-nitrobenzyl moiety is well-demonstrated in the enediyne analogues $\mathbf{2}$ and $\mathbf{3}$, where only the 4 -nitrobenzyl isomer $\mathbf{3}$ was a substrate for the enzyme. ${ }^{14}$
Factors of prime importance in the design of effective 4-nitrobenzyl carbamate prodrugs for nitroreductase-mediated prodrug therapy include the efficiency of the trigger unit as an

enzyme substrate and the rate of fragmentation following enzymic reduction. While kinetic structure-activity relationships (SAR) have been extensively studied for the one-electron reduction of nitrobenzyl halides ${ }^{3}$ and quaternary salts, ${ }^{2}$ the SAR involved in the reductive fragmentation of 4-nitrobenzyl carbamates has been neglected, with only the unsubstituted 4-nitrobenzyl derivatives being employed as prodrugs for NTR activation. The use of substituents on the nitrobenzyl moiety offers the prospect of modifying the rate of fragmentation of the reduced prodrug, and also providing a site of attachment for solubilising functionality.

In this paper we use a series of model compounds $\mathbf{4 a - n}$ to study the effect of nitrobenzyl substituents on the rate of fragmentation of the intermediate hydroxylamines 5a-n (generated by radiolysis) to release amines $\mathbf{6}$ or 7 (Scheme 2). Substituents

at both the 2 - and 3 -positions were selected to span a wide range of electronic properties, while also being able to serve as potential attachments for soluble side chains. The use of $\alpha$-substituents was also expected to alter the rate of fragmentation and may be a useful site for the attachment of solubilising groups. ${ }^{17}$ The amines 6 and 7, released on fragmentation of $\mathbf{4 a - n}$, were designed as simple models of cyclopropylindoline and enediyne (e.g. 3) prodrugs, while also being stable, synthetically accessible, water-soluble, and possessing a good UV signature for HPLC analysis.

## Results and discussion

## Synthesis of carbamates 4

Nitrobenzyl alcohols 8a and $\mathbf{8 k}$ for the preparation of the model carbamates were available commercially, and $\mathbf{8 d}, \mathbf{8 e}, \mathbf{8 g}$, 81 were prepared directly by borane-dimethyl sulfide $\left(\mathrm{BH}_{3}\right.$. DMS) reduction of the corresponding acids. 1-(4-Nitrophenyl)ethyl alcohol $8 \mathbf{c}^{18}$ and 2,4-dinitrobenzyl alcohol $\mathbf{8 j}{ }^{19}$ were

8
obtained as reported. 2-Methoxy-4-nitrobenzyl alcohol $\mathbf{8 f}$ was conveniently prepared by methylation of 4-nitrosalicylic acid 9 and diisobutylaluminium hydride (DIBAL-H) reduction of the resulting ester $\mathbf{1 0}$ (Scheme 3).

2-( $N$-Methyl- $N$-tert-butyloxycarbonylamino)-4-nitrobenzoic acid 8 h was prepared from 4-nitroanthranilic acid $\mathbf{1 1}$ by esterification to give $\mathbf{1 2}$, reductive methylation of the amine to give $\mathbf{1 3}$ and protection of $\mathbf{1 3}$ with the tert-butyloxycarbonyl (Boc) moiety to give the ester 14 (Scheme 4). Alkaline hydrolysis of 14

gave the acid $\mathbf{1 5}$ which was reduced to $\mathbf{8 h}$. Similarly, the isomer $\mathbf{8 i}$ was synthesized from the corresponding amine $\mathbf{1 7}$, prepared via a Curtius rearrangement from the 4-nitroisophthalic acid half ester 16, through intermediates 18-20 (Scheme 5).

The amine 7 was readily available (Scheme 6) from methyl 4nitrophenylacetate 21 by catalytic reduction and reductive amination to $\mathbf{2 2}$. Protection of $\mathbf{2 2}$ as the Boc derivative 23, hydrolysis of the ester and coupling of the resulting acid 24 with $N, N$-dimethylaminoethylamine provided the amide 25 . This was deprotected to give 7 , which was conveniently stored as the hydrochloride salt. The amine $\mathbf{6}$ was prepared by coupling 4-nitrophenylacetic acid 26 with $N, N$-dimethylaminoethylamine followed by catalytic reduction of the amide 27 and conversion to the hydrochloride salt (Scheme 7).

The majority of the model carbamates 4 were prepared by in situ formation of the chloroformate of the alcohols 8 and subsequent reaction with the amino ester 22 or methyl 4 -aminophenylacetate to give the carbamate esters 28. Basic

hydrolysis of $\mathbf{2 8}$ to the acids $\mathbf{2 9}$, followed by $1,1^{\prime}$-carbonyldiimidazole (CDI)-mediated coupling with $N, N$-dimethylaminoethylamine, gave carbamates 4 (Method A, Scheme 8). Carbamates $\mathbf{4 j}, \mathbf{4 k}$, and $\mathbf{4 I}$ were not obtainable by Method A because of decomposition under the reaction conditions, and were made instead by direct coupling of the corresponding alcohols $\mathbf{8 j}, \mathbf{8 k}$, and $\mathbf{8 l}$ to the amide $\mathbf{7}$, with purification by semipreparative HPLC (Method B, Scheme 9). Finally, carbamates $\mathbf{4 m}$ and $\mathbf{4 n}$ were made by direct HCl -mediated removal of the Boc group from $\mathbf{4 f}$ and $\mathbf{4 g}$, respectively (Method C, Scheme 10).

## Radiolytic reduction of carbamates 4

Radiolytic reduction, rather than enzymic reduction by $E$. coli NTR enzyme, was used in order to investigate the substituent effects on carbamate fragmentation without the complicating influence of the kinetics of enzyme activation. The radiolysis of water is a useful method to study reductivelytriggered reactions in aqueous media, because powerful, transient reductants can be generated in controlled quantities (via the exposure time of a given volume of solution at a known dose-rate) in solutions buffered over a wide pH range (2-11). It also provides information on the stoichiometry of reductive fragmentation, and hence the identity of the activated species that undergoes fragmentation. ${ }^{60} \mathrm{Co} \gamma$-rays produce approximately equal amounts of reducing aquated electrons ( $\mathrm{e}^{-}{ }_{\mathrm{aq}}$ ) and oxidising hydroxyl radicals $\left(\mathrm{OH}^{+}\right)$in water, and the presence of propan-2-ol produces a reducing environment by converting hydroxyl radicals to reducing 2 -hydroxypropan-2yl radicals, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}^{\circ} \mathrm{OH}$.

A typical plot of the change in the composition of an aqueous solution $(50 \mu \mathrm{M})$ of carbamate $\mathbf{4}$ with the extent of reductive activation by ${ }^{60} \mathrm{Co} \gamma$-rays is shown in Fig. 1. Up to 6 stoichiometric equivalents of reducing radicals were added, and the compositions of the reduced solutions were examined by HPLC. Fig. 1 shows that $\mathbf{4 b}$ is consumed with 4 -fold stoichiometry, generating a transient species assumed to be the corresponding hydroxylamine $\mathbf{5 b}$. The instability of these compounds precluded formal identification, but reactions of $\mathbf{5 b}$ with $\mathrm{Na}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{5} \mathrm{NH}_{3}\right]$ [sodium amminepentacyanoferrate(II)] are consistent with a hydroxyamino or nitroso compound. ${ }^{20}$ There was also proportional release of the corresponding amine $\mathbf{6}$ or $\mathbf{7}$ with up to 4 reducing equivalents, but little further release if more than 4 reducing equivalents were used. The subsequent production of amine $\mathbf{7}$ after reduction of $\mathbf{4 b}$ to the hydroxylamine $\mathbf{5 b}$ may be attributed to the slow fragmentation kinetics of $\mathbf{5 b}\left(\mathrm{M} t_{1 / 2}=16 \mathrm{~min}\right)$.

These data were used to estimate the maximum half-life $\left(\mathrm{M} t_{1 / 2}\right)$ of the hydroxyaminobenzyl carbamates 5. Assuming first order conditions, half-life $\left(t_{1 / 2}\right)$ is calculated from the equation $\ln \left([R]_{0} /[R]_{t}\right)=t\left(\ln 2 / t_{1 / 2}\right)$, where $[R]$ is the concentration of reactant at time $t$. Approximately 12 minutes were required to effect 4-electron reduction and assay the samples, thus only the fraction of the reduced carbamate which had not fragmented within 12 minutes could be calculated and substituted into the above equation. This gave an estimate of the maximum half-life of 5, and these data are presented in Tables 1-3. Solutions of the nitrobenzyl carbamates $4(50 \mu \mathrm{M}, \mathrm{pH} 7.4,10$ mm phosphate buffer, $4 \%(\mathrm{v} / \mathrm{v})$ propan-2-ol, $20^{\circ} \mathrm{C}$ ) were reduced with 4-fold stoichiometry and assayed for 5 by HPLC either immediately ( $c a .12$ minutes after reduction was commenced) to give $t_{0}$, or after ten half-lives to give $t_{\infty}$.

occurred with 4-fold stoichiometry, which is consistent with reduction to the hydroxylamine 5 . While all of the initial carbamates 4 were consumed after the addition of 4 reducing equivalents, only about $50 \%(22-68 \%)$ of the expected amines were produced at the earliest analysis time (assigned $t_{0}$ ) (Tables $1-3$ ). When the reduced solutions were maintained under anaerobic conditions at $20^{\circ} \mathrm{C}$ for a further 10 half-lives (assigned $t_{\infty}$ ), the presence of 5 was undetectable, yet little further amine was released. The unstable nature of $\mathbf{5}$ and the finite time required for its radiolytic generation, prevented quantification of chromatographic peaks and the direct measurement of the rate of fragmentation. Rather, quantification of the amine $\mathbf{6}$ or $\mathbf{7}$ released from $\mathbf{4}$ after reduction with 4 reducing equivalents was used to estimate the maximum halflife ( $\mathrm{M} t_{1 / 2}$ ) for the fragmentation of hydroxylaminobenzylcarbamates 5. Assuming first order conditions, the half-life $\left(t_{1 / 2}\right)$ of species R is calculated from the equation $\ln \left([R]_{0} /[R]_{t}\right)=$ $t\left(\ln 2 / t_{1 / 2}\right)$. The ratio $[R]_{0} /[R]_{t}$ was taken as the fraction of nitrobenzyl carbamate $\mathbf{4}$ which had not released amine $\mathbf{6}$ or $\mathbf{7}$ after 4-fold reduction; i.e., $[R]_{0}=50 \mu \mathrm{M}$ (the concentration of the nitrobenzyl carbamate 4 before radiolytic reduction), $[R]_{t}=50 \mu \mathrm{M}-$ [amine $_{t}$, and $t=$ time between beginning 4-fold reduction and measuring the concentration of 6 or 7 by HPLC (approximately 12 minutes). This method yields a maximum value for the half-life of fragmentation. The rate of reduction and of fragmentation both contribute to the rate of amine release, but the two sequential processes are combined within the $\mathrm{M} t_{1 / 2}$ value. However, the rate of reduction is constant (dictated by the dose rate of the $\gamma$-rays), and $\mathrm{M} t_{1 / 2}$ indicates the relative rates of amine release via 5 which are presented in Tables 1-3.

## Structure-activity relationships

The unsubstituted hydroxyaminobenzyl carbamate 5b (generated from $\mathbf{4 b}$ ) had a $\mathrm{M} t_{1 / 2}$ of 16 minutes (Table 1). This is relatively long, and under biological conditions may permit substantial loss of material by side reactions not involving (activating) amine release. The $\alpha$-methyl analogue 5 c had a $\mathrm{M} t_{1 / 2}$ of 9.5 min . This significant acceleration of fragmentation is presumably due to stabilisation of developing positive charge on the benzylic carbon. Compound $\mathbf{5 a}$ which releases a primary amine 6 fragmented about twice as rapidly ( $\mathrm{M} t_{1 / 2}=10$ minutes) as $\mathbf{5 b}$, indicating the nature of the leaving amine ( $\mathbf{6}$ instead of 7 ) also has some effect.

The remaining compounds (Tables 2 and 3) all released amine 7, so that carbamate substituent effects alone could be discerned. In support of the proposed mechanism, electrondonating substituents at the 2-position on the benzyl ring also accelerated fragmentation, presumably by a similar effect. Thus the electron-donating $2-\mathrm{OMe}(\mathbf{5 f}), 2-\mathrm{NHMe}(\mathbf{5 m})$ and $3-\mathrm{NHMe}$ (5n) analogues were more unstable than the parent compound $5 \mathrm{c}\left(\mathrm{M} t_{1 / 2}\right.$ values of $12,7.2$ and 14 min , compared with 16 $\min )$. Conversely the strongly electron-withdrawing 2-NO 2 and 3- $\mathrm{NO}_{2}$ substituents significantly slowed fragmentation of $\mathbf{5 j}$ and
$\mathbf{5 k}$ ( $\mathbf{M} t_{1 / 2}$ values of 88 min and 65 min respectively). In the case of these compounds it is not known unequivocally which nitro group undergoes reduction.

The 2 - and 3 -Me derivatives $\mathbf{5 d}$ and $\mathbf{5 e}$ fragmented, with apparent 3 -fold stoichiometry, too quickly to measure under our assay system. For the 12 compounds for which data was available, there was a quantitative relationship between $\mathrm{M} t_{1 / 2}$ and substituent electronic properties, measured as $\sigma_{p}$ for 2 -substituents and $\sigma_{m}$ for 3 -substituents [eqn. (1)] ( $n$ is the sample number, $r$ is the Pearson coefficient, $s$ is the standard error estimate and F is the F statistic for Goodness of Fit.

\end{gather*}
$$

Note that, while the five 2 -substituted analogues should ideally be represented by $\sigma_{\mathrm{o}}$ substituent constants, these are not readily available. Reliable $\sigma_{o}$ values are reported ${ }^{21}$ for only three of the five substituents, and these do not differ markedly ( $>25 \%$ ) from the corresponding $\sigma_{p}$ values. A recalculation of eqn, (1) using these values (not shown) did not change the conclusions to be drawn from it.
If the correlations are performed separately for the 2 - and 3 -substituted analogues, the intercept is identical but the $\sigma$ coefficient differs ( 0.67 for the 2 - substituted, 0.46 for the 3 - substituted). This greater dependence of the 2 -substituted compounds on substituent electronic properties would be consistent with some resonance stabilisation of the putative developing benzylic cation in the transition state of the carbamate fragmentation.

The extent of release of amine 7 after 10 half-lives ( $\mathrm{t}_{\infty}$ ) was clearly increased with increasing substituent electron-donation. Thus the 2 -NHMe analogue $\mathbf{5 m}$ produced a maximum of $71 \%$ of $\mathbf{7}\left(t_{\infty}\right)$ whereas the $2-\mathrm{NO}_{2}$ derivative $\mathbf{5 j}$ produced a maximum of only $33 \%$ of 7 . This property also correlated significantly with $\sigma$ values, although the relationship was not as strong [eqn. (2)], and is more difficult to understand.

$$

The varying degree of release of the amine (as low as $25 \%$ in some cases) is of concern. Prodrugs of low $\mathrm{p} K_{\mathrm{A}}$ effectors release to the least extent, with fragmentation of the hydroxylamine competing with another reaction that forms an unknown species. The nature of this species is currently under study.

These data suggest that the standard 4-nitrobenzyl carbamate trigger for NTR prodrugs may be improved upon. Electron-donating substituents in the 2-position and $\alpha$-methyl substitution of the nitrobenzyl moiety will both favour accelerated fragmentation of the 4 -hydroxylamines produced by enzymic reduction. Substituents such as 2 -alkoxy or 2 -aminoalkyl also provide potential linkage points for the attachment of side chains designed to improve prodrug solubility. Of course, the effect of such substitutions on the kinetics of enzymic reduction would have to be determined. Rates of hydroxylamine fragmentation are also likely to be influenced by the nature of the released amine, with prodrugs of primary amines fragmenting more rapidly than a comparable secondary amine. However, there may be less flexibility to alter the amine-based "effector".

## Preparation of methyl esters 28a-i. General method

Alcohol $\mathbf{8}$ was converted to the chloroformate by adding a solution of phosgene (CAUTION) in benzene ( 10 mmol ) dropwise to a stirred solution of $\mathbf{8}(2 \mathrm{mmol})$ in THF $\left(50 \mathrm{~cm}^{3}\right)$ at $0^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$. The solution was stirred at $20^{\circ} \mathrm{C}$ for 16 h and the solvent removed under reduced pressure. The residue was dissolved in DMF $\left(20 \mathrm{~cm}^{3}\right), \mathrm{Cs}_{2} \mathrm{CO}_{3}(2.5 \mathrm{mmol})$ and a solution of amine 6 or $7(2.2 \mathrm{mmol})$ in DMF ( $5 \mathrm{~cm}^{3}$ ) added. The mixture was stirred at $20^{\circ} \mathrm{C}$ for 16 h , poured into water $\left(100 \mathrm{~cm}^{3}\right)$, and extracted with EtOAc ( $3 \times 50 \mathrm{~cm}^{3}$ ). The combined organic extract was washed with $1 \mathrm{~m} \mathrm{HCl}\left(2 \times 50 \mathrm{~cm}^{3}\right)$, water $\left(50 \mathrm{~cm}^{3}\right)$, brine ( $40 \mathrm{~cm}^{3}$ ), dried, and the solvent removed under reduced pressure. The residue was chromatographed, eluting with a gradient ( $20-50 \%$ ) of EtOAc-light petroleum to give the ester 28. Yields and characterisations of individual compounds are given below.

## Hydrolysis of esters 28a-i. General method

A solution of ester $28(2 \mathrm{mmol})$ in $\mathrm{MeOH}\left(40 \mathrm{~cm}^{3}\right)$ and 1 m NaOH solution ( 10 mmol ) was stirred at $20^{\circ} \mathrm{C}$ for 1 h . The solution was washed with ether $\left(20 \mathrm{~cm}^{3}\right)$, the pH of the aqueous fraction adjusted to 2 with 5 m HCl , and extracted with EtOAc $\left(3 \times 30 \mathrm{~cm}^{3}\right)$. The combined organic extract was dried and the
solvent removed under reduced pressure. The solid was recrystallised from EtOAc to give acid 29. Yields and characterisations of individual compounds are given below.

## Formation of carbamates 4a-i: example of general preparation by method A (Scheme 8)

A solution of acid $29(1 \mathrm{mmol})$ and CDI ( 1.5 mmol ) in DMF $\left(10 \mathrm{~cm}^{3}\right)$ was heated at $50^{\circ} \mathrm{C}$ for $10 \mathrm{~min} . N^{\prime}, N^{\prime}$-Dimethylaminoethylamine ( 2 mmol ) was added and the solution stirred at $20^{\circ} \mathrm{C}$ for 2 h . The solution was poured into ice-water $(100$ $\mathrm{cm}^{3}$ ) and extracted with EtOAc ( $3 \times 50 \mathrm{~cm}^{3}$ ). The combined organic fraction was washed with 1 m NaOH solution $\left(10 \mathrm{~cm}^{3}\right)$, water $\left(3 \times 30 \mathrm{~cm}^{3}\right)$, brine $\left(30 \mathrm{~cm}^{3}\right)$, dried, and the solvent removed under reduced pressure. The residue was chromatographed on neutral alumina, eluting with EtOAc to give the amide 4. Amide $\mathbf{4}$ was dissolved in $\mathrm{MeOH}\left(10 \mathrm{~cm}^{3}\right)$ and $\mathrm{HCl}-$ saturated $\mathrm{MeOH}\left(10 \mathrm{~cm}^{3}\right)$ added and then the solvent was removed under reduced pressure to give 4 as the HCl salt. Yields and characterisations of individual compounds are given below.

## Formation of carbamates $\mathbf{4 j - 1}$ : example of general preparation by method B (Scheme 9)

A solution of the chloroformate of the alcohol $\mathbf{8}(2 \mathrm{mmol})$ in THF ( $50 \mathrm{~cm}^{3}$ ) was prepared in situ using phosgene and the alcohol $\mathbf{8}$ as described in Method A above. To this solution amine 7 in THF ( $5 \mathrm{~cm}^{3}$ ) was added and the solution stirred at
$20^{\circ} \mathrm{C}$ for 16 h . The solution was poured into sat. aq. $\mathrm{NaHCO}_{3}$ solution ( $100 \mathrm{~cm}^{3}$ ), and extracted with EtOAc ( $3 \times 50 \mathrm{~cm}^{3}$ ). The combined organic extract was dried and the solvent removed under reduced pressure. The residue was chromatographed on neutral alumina, eluting with a gradient $(0-10 \%) \mathrm{MeOH}-$ EtOAc, to give the carbamate 4. Final purification was achieved by semi-preparative reverse phase HPLC using a Philips PU4100 liquid chromatograph, a Phenomenex Bondclone 10 C18 column ( $300 \times 21.2 \mathrm{~mm}$ id) monitoring at 254 nm . Chromatograms were run in $50 \%$ acetonitrile-ammonium formate at $10 \mathrm{~cm}^{3} \mathrm{~min}^{-1}$. Yields and characterisations of individual compounds are given below.

Formation of carbamates $\mathbf{4 m}, \mathrm{n}$ : example of general preparation by method C (Scheme 10)

HCl -saturated $\mathrm{MeOH}\left(10 \mathrm{~cm}^{3}\right)$ was added to a stirred solution of $\mathbf{4 h}$ or $\mathbf{4 i}(0.26 \mathrm{mmol})$ in $\mathrm{MeOH}\left(10 \mathrm{~cm}^{3}\right)$ and the solution stirred at $20^{\circ} \mathrm{C}$ for 4 h . The solvent was removed under reduced pressure and the residue dissolved in water $\left(10 \mathrm{~cm}^{3}\right)$, the pH adjusted to 10 with aq. $\mathrm{Na}_{2} \mathrm{CO}_{3}$ solution, and extracted with $\mathrm{CHCl}_{3}\left(3 \times 25 \mathrm{~cm}^{3}\right)$. The combined organic extracts were
washed with brine ( $30 \mathrm{~cm}^{3}$ ), dried, and the solvent removed under reduced pressure. The residue was chromatographed on neutral alumina, eluting with a gradient $(0-10 \%) \mathrm{MeOH}-$ EtOAc, to give the carbamate 4. ## Radiolytic reduction of nitrobenzyl carbamates $\mathbf{4 a - n}$

Solutions of the carbamates $\mathbf{4}(50 \mu \mathrm{M})$ in 10 mm phosphate buffer ( $5 \mathrm{~cm}^{3}, \mathrm{pH} 7.4$ ) and propan-2-ol ( $4 \%, \mathrm{v} / \mathrm{v}$ ) were degassed by evacuation under reduced pressure, and radiolytically reduced at $20^{\circ} \mathrm{C}$ by $\gamma$-irradiation, using a ${ }^{60} \mathrm{Co}$ source. The dose rate of the ${ }^{60} \mathrm{Co}$ source was measured as $0.721 \mathrm{~J} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$ using the NaCl modified Fricke dosimeter, ${ }^{25}$ and corrected for decay of ${ }^{60} \mathrm{Co}$ in subsequent irradiations. The time, $t$, required to form 1 molar equivalent of reducing species in a solution of prodrug ( $50 \mu \mathrm{M}, 5 \mathrm{~cm}^{3}$ ) was calculated from $t=n /(G d v)$, where $n=$ mole of prodrug, $G=$ radiation chemical yield (taken as $0.62 \mu \mathrm{~mol}$ $\left.\mathrm{J}^{-1}, G\left(\mathrm{e}^{-}{ }_{\text {aq }}\right)+G\left({ }^{\circ} \mathrm{H}\right)+G(\mathrm{OH})\right) d=$ dose rate and $v=$ the volume of radiolysis solution. Samples were analysed by HPLC, injecting $0.05 \mathrm{~cm}^{3}$ samples through a $0.025 \mathrm{~cm}^{3}$ sample loop, on an Econosphere C-18 analytical column (reverse phase, $5 \mu \mathrm{~m}$ particle size, $250 \times 4.6 \mathrm{~mm}$ id). Samples were eluted using both gradient and isocratic solvent systems, comprised of mixtures of $\mathrm{MeOH}, \mathrm{pH} 6.5,10 \mathrm{~mm}$ phosphate buffer and 10 mm heptane sulfonic acid, at a flow rate of $0.8 \mathrm{~cm}^{3} \mathrm{~min}^{-1}$. An HP1040M series II detector permitted collection of the spectra of chromatographic peaks. HPLC was used to quantify the release of amines 6 or 7, using authentic samples to prepare calibration plots.
