Sulfobacin A (1), B (2), and flavocristamide A (3), new sulfonolipids isolated from Chryseobacterium sp. were synthesized stereoselectively by starting from L-cysteine.

## Introduction

In 1995 sulfobacin A (1) and B (2), von Willebrand factor

receptor antagonists, were isolated by Kamiyama et al. from the culture broth of Chryseobacterium sp. ${ }^{2}$ Almost simultaneously, the isolation of flavocristamide A (3) and B (= sulfobacin A, 1), DNA polymerase $\alpha$ inhibitors, from the cultured mycelium of Flavobacterium sp. (=Chryseobacterium sp.) was reported by Kobayashi et al. ${ }^{3}$ These compounds are novel sulfonolipids and are unusual sphingosine derivatives. Similar sulfonolipids, $N$-acyl-2-amino-3-hydroxy-15-methylhexadecane-1-sulfonic acids, were previously found in the cell envelope of gliding bacteria of the genera Cytophaga, Capnocytophaga, Sporacytophaga and Flexibacter. ${ }^{4,5}$ Although a structurally similar sulfonolipid was previously synthesized by Kamikawa et al., ${ }^{6}$ the synthesis of these sulfonolipids (1,2 and 3) had not been reported. We therefore became interested in synthesizing these three compounds as a part of our work in preparing unusual sphingosine derivatives. ${ }^{7}$ Recently, two syntheses of sulfobacins were reported as preliminary communications. The first one was carried out by Irako and Shioiri, ${ }^{8}$ and the second was accomplished by us. ${ }^{9}$ Herein we describe our improved synthesis of sulfobacins and the details of the first synthesis of flavocristamide A (3).

## Results and discussion

## Synthetic plan

Scheme 1 shows our synthetic plan for $\mathbf{1}$. The target compound
$\mathbf{1}$ can be prepared from an aminosulfinic acid $\mathbf{A}$, which is obtainable from the key intermediate B. Since the sulfone portion of $\mathbf{B}$ is a part of the acetonide group, this is considered a sulfinic acid equivalent. The key intermediate $\mathbf{B}$ may be synthesized by diastereoselective coupling of $\mathbf{C}$ with $\mathbf{D}$. For the preparation of optically active $\mathbf{E}$, we adopt enzymatic resolution. This synthetic plan could also be applicable for the synthesis of the other two target compounds ( $\mathbf{2}$ and $\mathbf{3}$ ).

## Synthesis of the key intermediates B and E

First we synthesized the intermediate $\mathbf{E}(=\mathbf{8 b})$ as follows. 10-Bromodecan-1-ol 4 was treated with isoamylmagnesium bromide in the presence of dilithium tetrachlorocuprate $\left(\mathrm{Li}_{2} \mathrm{CuCl}_{4}\right)$ to give alcohol 5 (Scheme 2). This was then oxidized to give either the corresponding aldehyde 6 or the carboxylic acid 7. The aldehyde $\mathbf{6}$ was treated with the lithium enolate of ethyl acetate followed by hydrolysis to give $( \pm)-\mathbf{8 b}(=\mathbf{E})$. This racemate was resolved with lipase PS in the presence of vinyl acetate ${ }^{10}$ to afford the desired $(R)-\mathbf{8 b}$ in $28 \%$ yield, $[a]_{D}^{23}=-12.7$ (c 1.02 in $\mathrm{CHCl}_{3}$ ) $\left\{\right.$ lit. ${ }^{11}[a]_{\mathrm{D}}^{20}=-12.0$ (c 1.0 in $\left.\left.\mathrm{CHCl}_{3}\right)\right\}$. The enantiomeric purity of $(R)$-8 was estimated by GLC analysis on a chiral stationary phase to be $\sim 100 \%$ ee. The hydroxy acid ( $R$ )$\mathbf{8 b}$ was then converted into the corresponding TBDMS ether 9 .

We then prepared the intermediate $\mathbf{D}(=\mathbf{1 2 )}$ as follows. Commercially available dec-9-en-1-ol 10a was treated with toluene-$p$-sulfonyl chloride ( TsCl ), which was employed in a Grignard coupling with isobutylmagnesium bromide in the presence of $\mathrm{Li}_{2} \mathrm{CuCl}_{4}$ to afford 11. Dibromination of $\mathbf{1 1}$ was followed by dehydrobromination ${ }^{12}$ to give 12. ${ }^{13}$

The known aldehyde $\mathbf{1 4}^{14}(=\mathbf{C})$ was prepared from L-cysteine hydrochloride 13. At that time we found that the enantiomeric purity of the obtained $\mathbf{1 4}$ (after chromatographic purification) was $93 \%$ ee, and that of the crude $\mathbf{1 4}$ was $\sim 100 \%$ ee by HPLC analysis. The decrease of enantiomeric purity could be due to the partial racemization of aldehyde 14 in the course of the purification. We therefore decided to employ 14 in the next step without purification. Diastereoselective addition of lithium alkynide derived from 12-methyltridec-1-yne (12) to $\mathbf{1 4}$ was performed by Fujisawa's procedure ${ }^{14}$ to give the desired antiadduct 15 in $65 \%$ yield ( 2 steps) after chromatographic separation (anti:syn =ca. 6:1). The enantiomeric purity of $\mathbf{1 5}$ was determined by HPLC analysis to be $95 \%$ ee. After reduction of the triple bond, the sulfur atom at the thiazolidine ring was oxidized with MCPBA to afford the key intermediate 17 (= B). At this stage an alternative route to $\mathbf{1 7}$ was also examined. The known ester $18{ }^{15}$ was oxidized with MCPBA to give 19. First we attempted to prepare aldehyde 21 by the reduction of 19 with DIBAL-H. Although the reaction proceeded cleanly, the enantiomeric purity of the resulting 21 (after chromatographic

Scheme 1 Synthetic plan for 1.
purification) was $<20 \%$ ee and that of the crude 21 was ca. $60 \%$ ee. The following reduction-oxidation sequence was therefore chosen. The ester 19 was reduced with LAH, which was followed by oxidation with Dess-Martin periodinane ${ }^{16}$ to give aldehyde 21. The enantiomeric purity of the resulting 21 (without purification) was estimated to be $\sim 100 \%$ ee by HPLC analysis. This aldehyde 21 was immediately employed in diastereoselective addition of lithiated $\mathbf{1 2}$ to give $\mathbf{2 2}$ in $65 \%$ yield under the same conditions as for the preparation of $\mathbf{1 5}$. Although the chemical yield was moderate, the diastereoselectivity was excellent (anti:syn =99:1). Several attempts were made in vain to improve the yield of $\mathbf{2 2}$ by using differently metallated $\mathbf{1 2}$. The triple bond of $\mathbf{2 2}$ was then reduced to give 17. The enantiomeric purity of $\mathbf{1 7}$ was estimated to be $97.8 \%$ ee by HPLC analysis. Judging from the overall efficiency, it was concluded that the latter procedure was more efficient and practical for the preparation of $\mathbf{1 7}$.

## Synthesis of sulfobacin A and B

The next step is one of the key steps in our synthesis. As mentioned in the synthetic plan, the sulfone portion of $\mathbf{1 7}(=\mathbf{B})$ is a part of the acetonide group and is thought of as a sulfinic acid equivalent. Therefore deprotection of the acetonide group should give the corresponding sulfinic acid. This idea was realized as follows. The cleavage of Boc and acetonide protecting groups of $\mathbf{1 7}$ was achieved by treatment with hydrochloric acid to give crystalline sultine 23, ${ }^{17}$ not sulfinic acid (A) (Scheme 3). The formation of the cyclic sulfinate was not expected but welcome to us nevertheless, because it also served as the protection for the hydroxy group. Moreover, the enantiomeric purity of $\mathbf{2 3}$ could be enriched to $\sim 100 \%$ ee by recrystallization at this stage. The orientation of the oxygen atom on the sulfur atom of 23 was determined to be $\beta$ on the basis of the similarity of its ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum to that of $\mathbf{2 9 a}$ (vide infra). The amino group of $\mathbf{2 3}$ was acylated with 7 in the presence of DCC to give the amide 24. Hydrolysis of the sulfinate portion with aqueous
ammonia was followed by oxidation with hydrogen peroxide to furnish sulfobacin $\mathbf{B}(2),[a]_{D}^{20}=-10.7\left(c 0.14\right.$ in MeOH) $\left\{\right.$ lit. ${ }^{2}$ $[a]_{\mathrm{D}}^{23}=-19(c 0.14$ in MeOH$\left.)\right\}$. The overall yield of $\mathbf{2}$ was $28 \%$ prepared in 9 steps starting from 18. Although the reason for the disagreement in the optical rotation value is not clear, the ${ }^{1} \mathrm{H}-\mathrm{NMR},{ }^{13} \mathrm{C}-\mathrm{NMR}$, IR and mass spectra of synthetic $\mathbf{2}$ were in good accord with those reported. Indeed the direct comparison of our spectra with the copies of the spectra of the natural product fully supported the identity of our synthetic $\mathbf{2}$ as sulfobacin B.

By the same procedure as described above, sulfobacin A (1) was also synthesized. The aminosultine 23 was acylated with 9 to give 26a. The deprotection of the TBS group of 26a afforded 26b. The resulting 26b was converted to sulfobacin A (1) in 2 steps, $[a]_{\mathrm{D}}^{25}=-15\left(c 0.14\right.$ in MeOH), $\left\{\right.$ lit. ${ }^{2}[a]_{\mathrm{D}}^{24}=-35(c 0.14$ in $\mathrm{MeOH})$, lit. ${ }^{3}[a]_{\mathrm{D}}^{20}=-7.9(c 0.18$ in MeOH$\left.)\right\}$. The overall yield of $\mathbf{1}$ was $22 \%$ prepared in 10 steps starting from $\mathbf{1 8}$. The optical rotation value of synthetic 1 was not in good accord with those of Kamiyama's ${ }^{2}$ and Kobayashi's. ${ }^{3}$ To clarify the reason for the disagreement, we remeasured the optical rotation value of natural 1 kindly supplied by Kamiyama. It was not identical with that reported, $[a]_{D}^{18}=-8.1$ (c 0.10 in MeOH ). The optical rotation value of this type of compounds seems to be sensitive to temperature, pH and/or concentration. In addition, we prepared the sodium salt of $\mathbf{1}$ according to Kobayashi's advice and measured its optical rotation value. This was in good accord with that of Kobayashi's, $[a]_{\mathrm{D}}^{24}=-9.0(c 0.10$ in MeOH$)$. The ${ }^{1} \mathrm{H}$-NMR data of synthetic $\mathbf{1}$ was also slightly different from those reported. ${ }^{2,3}$ We therefore remeasured ${ }^{1} \mathrm{H}$-NMR spectra of Kamiyama's natural $\mathbf{1}$ and our synthetic $\mathbf{1}$ under almost the same conditions. These two spectra were superimposable supporting the conclusion that our synthetic 1 was identical with Kamiyama's natural 1. The ${ }^{13} \mathrm{C}-\mathrm{NMR}$, IR and mass spectra of synthetic $\mathbf{1}$ were also in good accord with those of Kamiyama's. We then measured ${ }^{1} \mathrm{H}$-NMR spectrum of the sodium salt of synthetic 1, and it was in good accord with that of Kobayashi's.
It was therefore concluded that Kamiyama's group isolated

sulfobacin A as the free sulfonic acid and Kobayashi's group isolated flavocristamide B (= sulfobacin A) as its sodium salt.

## Synthesis of flavocristamide A

The next subject we addressed was the synthesis of flavocristamide A (3). Attempts were initially made to prepare the intermediate $\mathbf{2 8}$ by reduction of $\mathbf{2 2}$. Although a variety of reduction conditions were examined, we could not find any appropriate conditions. We therefore turned our attention to using nucleophilic addition of alkenylmetal to $\mathbf{2 1}$ and carried out a series of experiments as shown in Table 1. The same conditions employed for the synthesis of $\mathbf{1 7}$ and $\mathbf{2 2}$ gave the desired diastereomer 28, although the chemical yield was less than $30 \%$ (Scheme 4). We therefore tried to use different alkenylmetals under various conditions (Table 1). As a result, the conditions listed in entry 5 were selected as those optimal to obtain 28.

Diastereoselective addition of 12-methyltridec-1-enylmagnesium bromide to $\mathbf{2 1}$ gave $\mathbf{2 8}$ in $67 \%$ yield. The diastereo-
selectivity was estimated by HPLC analysis to be anti:syn= 96:4. Cleavage of the Boc and the acetonide protecting groups of $\mathbf{2 8}$ gave aminosultines 29a and 29b as a mixture (ca. 4:1) in $96 \%$ yield. Based on the careful comparison of their ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra, the less polar and major product was thought to be 29a, while the other was 29b. MM3 calculations also supported our hypothesis. This mixture was acylated with 9 and then the products were separated by silica gel column chromatography to give amides 30a and 30b in $49 \%$ and $14 \%$ yield respectively. In the same manner as mentioned before, the two isomers 30a and 30b were finally converted to flavocristamide A (3), $[a]_{\mathrm{D}}^{22}=-21(c 0.27, \mathrm{MeOH})\left\{\mathrm{lit}^{2}{ }^{2}[a]_{\mathrm{D}}^{20}=-17(c 0.27, \mathrm{MeOH})\right\}$. The overall yield of $\mathbf{3}$ was $19 \%$ prepared in 9 steps starting from 18. The sodium salt of 3 was then prepared, $[a]_{D}^{18}=-16(c 0.10$ in MeOH ). Although the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of synthetic 3 (sulfonic acid) was slightly different from that reported, that of the sodium salt was in good accord with the reported data. The ${ }^{13} \mathrm{C}$-NMR, IR and mass spectra of synthetic $\mathbf{3}$ were also in good accord with those reported.

In summary, the syntheses of new sulfonolipids sulfobacin A (1), B (2) and flavocristamide A (3) were achieved by starting from l-cysteine. We have clarified that sulfobacin A (1) and B (2) isolated by Kamiyama and his co-workers were sulfonic acids and that flavocristamide A (3) and B (= sulfobacin A, 2) isolated by Kobayashi and his co-workers were sodium salts.

After the reaction mixture was concentrated under reduced pressure, the residue was chromatographed on $\mathrm{SiO}_{2}$ to give the sulfonic acid $\mathbf{3}(78 \mathrm{mg}, 95 \%$ based on 31a) as a white solid, $\mathrm{mp} 210-213^{\circ} \mathrm{C}$; $[a]_{\mathrm{D}}^{22}-21(c 0.27$ in $\left.\mathrm{CH}_{3} \mathrm{OH}\right) ; v_{\text {max }}($ film $) / \mathrm{cm}^{-1} 3300 \mathrm{~m}(\mathrm{OH}$ and NH$), 2940 \mathrm{~m}(\mathrm{CH})$, $2870 \mathrm{~m}(\mathrm{CH}), 1640 \mathrm{~s}(\mathrm{NHCO}), 1550 \mathrm{~s}(\mathrm{NHCO}), 1470 \mathrm{~s}, 1390 \mathrm{~m}$, $1370 \mathrm{~m}, 1200 \mathrm{~s}, 1060 \mathrm{~s}^{\left(\mathrm{SO}_{3}\right), 970 \mathrm{~m}, 805 \mathrm{~m}, 725 \mathrm{~m} ; \delta_{\mathrm{H}}(500 \mathrm{MHz} ; ~}$ $\left.\mathrm{CD}_{3} \mathrm{OD}\right) 0.87\left(12 \mathrm{H}, \mathrm{d}, J 6.7, \mathrm{CH}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.13-1.48(38 \mathrm{H}, \mathrm{m}$, $7-, 8-, 9-, 10-, 11-, 12-, 13-, 14-, 4^{\prime}-, 5^{\prime}-, 6^{\prime}-, 7^{\prime}-, 8^{\prime}-, 9^{\prime}-$, $10^{\prime}-, 11^{\prime}-, 12^{\prime}-, 13^{\prime}-$ and $\left.14^{\prime}-\mathrm{H}_{2}\right), 1.52\left(2 \mathrm{H}, \mathrm{m}, 15-\right.$ and $\left.15^{\prime}-\mathrm{H}\right)$, $2.05\left(2 \mathrm{H}, \mathrm{m}, 6-\mathrm{H}_{2}\right), 2.33\left(1 \mathrm{H}, \mathrm{dd}, J 14.6\right.$ and $\left.8.4,2^{\prime}-\mathrm{H}_{\mathrm{a}}\right), 2.38$ $\left(1 \mathrm{H}, \mathrm{dd}, J 14.6\right.$ and $\left.3.7,2^{\prime}-\mathrm{H}_{\mathrm{b}}\right), 2.89(1 \mathrm{H}$, dd, $J 14.3$ and 9.9 , $\left.1-\mathrm{H}_{\mathrm{a}}\right), 3.19\left(1 \mathrm{H}, \mathrm{dd}, J 14.3\right.$ and $\left.2.2,1-\mathrm{H}_{\mathrm{b}}\right), 3.97\left(1 \mathrm{H}, \mathrm{m}, 3^{\prime}-\mathrm{H}\right)$, $4.07(1 \mathrm{H}, \mathrm{t}, J 6.3,3-\mathrm{H}), 4.39(1 \mathrm{H}, \mathrm{m}, 2-\mathrm{H}), 5.46(1 \mathrm{H}, \mathrm{dd}, J 15.4$ and $6.9,4-\mathrm{H}), 5.74(1 \mathrm{H}, \mathrm{dt}, J 15.4$ and $6.8,5-\mathrm{H}) . \delta_{\mathrm{C}}(126 \mathrm{MHz} ;$ $\mathrm{CD}_{3} \mathrm{OD}$ ) 23.0, 26.8, 28.55, 28.58, 29.2, 30.4, 30.5, 30.7, 30.81, $30.83,30.9,31.07,31.1,33.5,38.1,38.4,40.26,40.28,44.7,52.3$, 52.4, 69.8, 74.9, 130.4, 135.4 [Found: (HRFAB-MS) (M - H) 616.4612. $\mathrm{C}_{34} \mathrm{H}_{66} \mathrm{NO}_{6} \mathrm{~S}$ requires $\left.m / z 616.4611\right]$.

## Sodium salt of 3

To $3(5.5 \mathrm{mg}, 0.0089 \mathrm{mmol})$ was added aq. $\mathrm{Na}_{2} \mathrm{CO}_{3}(8.1 \mathrm{mmol}$ $\mathrm{dm}^{-3} ; 0.55 \mathrm{~cm}^{3}$ ), and the mixture was concentrated under reduced pressure. The residue in $\mathrm{CHCl}_{3}$ was filtered through Celite, and the filtrate was concentrated under reduced pressure to give the sodium salt of $3,[a]_{\mathrm{D}}^{18}-16\left(c 0.10\right.$ in $\left.\mathrm{CH}_{3} \mathrm{OH}\right) ; \delta_{\mathrm{H}}(400$
