Regio- and stereo-selective ring-opening reactions of $N$-(2,4,6-trimethylphenylsulfonyl) $-\gamma, \delta$-cis- or -trans- $\gamma, \delta$-epimino ( $E$ )- $\alpha, \beta$-enoates with acids such as methanesulfonic acid (MSA) or trifluoroacetic acid (TFA) have been found. These ring-opening reactions are useful for the stereoselective synthesis of a couple of diastereomeric ( $E$ )-alkene dipeptide isosteres from a single substrate of $\gamma, \delta$-epimino $(E)-\alpha, \beta$-enoate, and for the convenient preparation of $\delta$-aminated $\gamma$-hydroxy $\alpha, \beta$-enoates.

## Introduction

The potential of $(E)$-alkene dipeptide isosteres as backbone replacements of amide bonds in peptides has been well documented among various dipeptide isosteres in the past few years. ${ }^{1} \mathrm{We}^{2}$ and others ${ }^{3}$ have recently reported that peptides containing ( $E$ )-alkene isosteres can exhibit potent biological activities. In order to facilitate structure-activity relationship studies on such peptide-lead candidates, development of new efficient methodology for the synthesis of $(E)$-alkene isosteres is needed. Since it has been reported that the stereochemistry at the $\alpha$-position and the ( $E$ )-configuration are important for biological activity, the stereocontrolled synthesis of both isomers of types $\mathbf{2}$ and $\mathbf{4}$ from a single substrate of type $\mathbf{1}$ would
be extremely valuable (Scheme 1). One advantage of such a strategy is that three other stereoisomeric enoates 5, 6, and $\mathbf{7}$ can be convergently transformed into the enoate $\mathbf{1}$ by exposure to a palladium(0)-catalyst (Scheme 1). ${ }^{4}$ We and others reported previously the two synthetic methods for diastereomerically pure ( $E$ )-alkene isosteres $\mathbf{2}$ and $\mathbf{8}$ by employing organocoppermediated anti-S $\mathrm{S}_{\mathrm{N}}{ }^{2}$ reactions of $\beta$-aziridinyl $\alpha, \beta$-enoate $\mathbf{1}^{5}$ and $\delta$-aminated $\gamma$-mesyloxy $\alpha, \beta$-enoate $\mathbf{9},{ }^{6}$ respectively.
As part of our investigations of peptide scaffold designs related to structure-activity relationship studies, we are particularly interested in ring-opening reactions of enoates of type $\mathbf{1}$ for the preparation of key intermediates $\mathbf{3}$ for the synthesis of dipeptide surrogates 4 . In this paper, we detail the regio- and stereo-specific ring-opening reactions of $\beta$-aziridinyl $\alpha, \beta$ -

enoates by methanesulfonic acid (MSA) and the stereoselective synthesis of $(E)$-alkene dipeptide isosteres by treatment of the ring-opened products with organocopper reagents. ${ }^{7}$ In addition, we also report our finding of similar ring-opening reactions by trifluoroacetic acid (TFA) and the application of such reactions to a convenient synthesis of homochiral $\delta$-aminated $\gamma$-hydroxy $\alpha, \beta$-enoates, such as a versatile building block for sphingosine synthesis.

The focus of this paper deals with regiospecific ringopening reactions of $\beta$-aziridinyl $\alpha, \beta$-enoates and their applications.

## Results and discussion

## Ring-opening reactions of $N$-(2,4,6-trimethylphenylsulfonyl) (Mts)- $\gamma, \delta$-epimino $\alpha, \beta$-enoates with MSA or TFA

Although there exist ample precedents demonstrating that various nucleophiles, ${ }^{8}$ containing acids such as acetic acid, ${ }^{9}$ TFA ${ }^{10}$ and toluene- $p$-sulfonic acid in aqueous acetone, ${ }^{11}$ attack simple N -activated or inactivated aziridines ${ }^{12}$ at either of two carbon atoms, yielding the corresponding ring-opened products, the practically useful reactions involving $\gamma, \delta$-epimino $\alpha, \beta$-enoates of type $\mathbf{1}$ with MSA or TFA have not been reported heretofore. We initially examined ring-opening reactions by MSA treatment of $N$-(2,4,6-trimethylphenylsulfonyl) (Mts)protected (and activated) aziridines bearing $\alpha, \beta$-unsaturated esters ${ }^{4,5}$ (Scheme 2). Exposure of the $N$-Mts $-\gamma, \delta-c i s-\gamma, \delta$ epimino ( $E$ )- $\alpha, \beta$-enoate $\mathbf{1 0}$, which was previously synthesized from l-valine, ${ }^{4}$ to MSA (10 equiv.) in $\mathrm{CHCl}_{3}$ at rt for 20 min afforded exclusively $\delta$-aminated $\gamma$-mesyloxy $\alpha, \beta$-enoate 11 in essentially quantitative yield, presumably via the regioselective
$\mathrm{S}_{\mathrm{N}} 2$ ring-opening reaction at the $\gamma$-carbon position. Furthermore, we investigated the feasibility of the ring-opening reactions by TFA treatment. The $c i s-(E)$-enoate $\mathbf{1 0}$ was exposed to TFA at rt for 15 h to afford exclusively the $\delta$-aminated $\gamma$-trifluoroacetoxy $\alpha, \beta$-enoate 12. Hydrolysis of $\mathbf{1 2}$ and silica gel flash chromatographic purification yielded the $\delta$-aminated $\gamma$-hydroxy $\alpha, \beta$-enoate 13 in $93 \%$ yield based on 10 (Scheme 2). It was found that the MSA-mediated ring-opening reaction proceeded much faster than the reaction involving TFA. In both cases, ring-opened products generated by nucleophilic attack at the $\alpha$ - or $\delta$-carbon position could not be detected. Regiochemical assignments for the mesyl ester 11 and the trifluoroacetate $\mathbf{1 2}$ were readily made by ${ }^{1} \mathrm{H}-\mathrm{NMR}\left({ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}\right.$ COSY). The $\gamma, \delta$-syn stereochemistry of the ring-opened product $\mathbf{1 3}$ was confirmed by transformation of $\mathbf{1 3}$ into the original substrate $\mathbf{1 0}$ using the Mitsunobu conditions. ${ }^{13}$ Since the mesyl compound $\mathbf{1 1}$ was prone to regenerate the original substrate $\mathbf{1 0}$ during silica gel flash chromatographic purification, it could not be isolated in an analytically pure form.

Next, ring-opening of three other stereoisomeric enoates 14, 18 and 19, which were previously synthesized from L-valine, ${ }^{4}$ was investigated. Regiospecific ring-opening was successfully carried out on the trans- $(E)$-isomer of the aziridine enoate 14 with MSA or TFA treatment in a similar manner, yielding 15 or 17, respectively (the isolated yield of 17 based on 14: $91 \%$ ). In both cases, ring-opened products generated by nucleophilic attack at the $\alpha$ - or $\delta$-carbon position could not be detected. Regiochemical assignments for the mesyl ester $\mathbf{1 5}$ and the trifluoroacetate 16 were readily made by ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY. The $\gamma, \delta$ anti stereochemistry of the ring-opened product 17 was confirmed by transformation of $\mathbf{1 7}$ into the original substrate 14 using the Mitsunobu conditions. ${ }^{13}$ Furthermore, stereo-

chemical assignments for diastereomers $\mathbf{1 3}$ and $\mathbf{1 7}$ were also easily established by conversion to the acetonide derivatives $\mathbf{2 0}$ and 21, respectively. The NOE data by NMR analyses of $\mathbf{2 0}$ and $\mathbf{2 1}$ are in good agreement with their stereochemistry. On the other hand, attempted treatment of the cis-( $Z$ )-enoate 18 and the trans-( $Z$ )-enoate 19 with MSA or TFA failed to afford the desired ring-opened products and, instead, gave complex mixtures containing the $\gamma$-butenolactones, 22 and 23, respectively. This clearly demonstrates that a slight difference in the structure of the substituents can significantly change the reaction route. Since the enoates 18 and 19 can be converted
into the enoate $\mathbf{1 0}$ via $\mathrm{Pd}(0)$-catalyzed reactions, ${ }^{4}$ this ringopening reaction incurs no significant problems in terms of its practical use for the preparation of $(E)$-alkene isosteres, although our methodology is not applicable to the synthesis of $(Z)$-alkene isosteres.

Synthesis of the other requisite $N$-Mts- $\gamma, \delta-c i s-\gamma, \delta$-epimino ( $E$ )$\boldsymbol{\alpha}, \boldsymbol{\beta}$-enoates (enamides)

As shown in Scheme 3, the diastereomerically pure $N$-Mts $-\gamma, \delta$ $c i s-\gamma, \delta$-epimino ( $E$-- $\alpha, \beta$-enoates (enamides) 31, 36, 44, 54 and

55, which were required for the synthesis of $(E)$-alkene dipeptide isosteres (amino alcohols), were readily prepared according to the known methods. ${ }^{4,5}$ Boc-d-Phe-OMe 24 was treated successively with diisobutylaluminium hydride (DIBAL), oxalyl dichloride- dimethyl sulfoxide (DMSO)- $N, N$ diisopropylethylamine (DIPEA) and vinylmagnesium chloride to give a separable 6:1 mixture of allyl alcohols 27 and 28. Exposure of $\mathbf{2 7}$ to TFA followed by successive treatments with $\mathrm{Mts}-\mathrm{Cl}$ in the presence of triethylamine $\left(\mathrm{Et}_{3} \mathrm{~N}\right)$, triphenyl-phosphine-diethyl azodicarboxylate (DEAD), ozone, dimethyl sulfide and [(methoxycarbonyl)methylene]triphenylphosphorane afforded a mixture of the ( $2 E$ )- and ( $2 Z$ )-enoate 31 and 32. By a palladium(0)-catalyzed reaction, ${ }^{4}$ a mixture of $\mathbf{3 1}$ and $\mathbf{3 2}$ was converted into the cis-( $E$ )-enoate 31 (for details, see Experimental section). Likewise, the allyl alcohol 33, which was previously synthesized, ${ }^{4}$ was treated successively with TFA, $\mathrm{Mts}-\mathrm{Cl}-\mathrm{Et}_{3} \mathrm{~N}, \mathrm{Ph}_{3} \mathrm{P}-\mathrm{DEAD}$, ozone, dimethyl sulfide, [(benzyloxycarbonyl)methylene]triphenylphosphorane and $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$ to give the cis-( $E$ )-enoate 36. $N^{e}$-2-Chlorophenylmethoxycarbonyl (Cl-Z)-protected Lys 37 was also successively treated with Mts-Cl-Et ${ }_{3} \mathrm{~N}$, 1-hydroxybenzotriazole (HOBt)-3-[3-(di-methylamino)propyl]-1-ethylcarbodiimide (WSCD)-N,O-dimethylhydroxylamine hydrochloride, DIBAL, vinylmagnesium chloride, $\mathrm{Ph}_{3} \mathrm{P}-\mathrm{DEAD}$, ozone, dimethyl sulfide, [(benzyloxycarbonyl)methylene]triphenylphosphorane and $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$ to yield the $c i s$ - $(E)$-enoate 44. $N$-Boc-( $(S)$-serinal acetonide 45 was successively treated with vinylmagnesium chloride, TFA- $\mathrm{H}_{2} \mathrm{O}$, Mts-Cl-DIPEA, benzyl bromide-sodium hydride and $\mathrm{Ph}_{3} \mathrm{P}-$ DEAD to give a diastereomixture of vinylaziridines $\mathbf{5 2}$ and 53 . Reaction of the mixture of $\mathbf{5 2}$ and $\mathbf{5 3}$ with ozone, dimethyl sulfide, $N$-methyl(diethylphosphono)acetamide-DIPEA and $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$ gave the cis-( $E$ )-enamide 54. Likewise, reaction of the mixture of 52 and 53 with ozone, dimethyl sulfide, [(methoxycarbonyl)methylene]triphenylphosphorane and Pd$\left(\mathrm{PPh}_{3}\right)_{4}$ gave the $c i s$ - $(E)$-enoate 55. The configuration of the $\gamma$ - and $\delta$-carbon centers and the $(E)$-stereochemistry for the double bonds in the above $N$-Mts- $\gamma, \delta$-epimino $\alpha, \beta$-enoates (enamide) were assigned on the basis of the NOE data and the coupling constants by NMR analyses. ${ }^{5}$

## Synthesis of $(E)$-alkene dipeptide isosteres using the ring-opening reaction with MSA

We examined the feasibility of the stereoselective synthesis of $(E)$-alkene dipeptide isosteres by treatment of the ring-opened products with organocopper reagents. Treatment of the above mesyl compound 11, which was prepared from the cis- $(E)$ enoate $\mathbf{1 0}$ by the MSA-mediated ring-opening reaction, with $\mathrm{BnCu}(\mathrm{CN}) \mathrm{MgCl} \cdot \mathrm{BF}_{3}$ (4 equiv.) in THF at $-78^{\circ} \mathrm{C}$ for 30 min yielded the protected (L-amino acid, D-amino acid)-type $(2 S, 5 S)$ dipeptide isostere, Mts-L-Val- $\psi[(E)$-CH=CH]-d-PheOMe, $\mathbf{5 6}$ in $94 \%$ yield based on $\mathbf{1 0}$ (diastereoselection > 99:1 from NMR analysis). This reaction occurred by an anti- $\mathrm{S}_{\mathrm{N}} 2^{\prime}$ mechanism as shown in Scheme 4. In contrast, an anti- $\mathrm{S}_{\mathrm{N}} 2^{\prime}$ reaction of the cis- $(E)$-enoate $\mathbf{1 0}$ with $\mathrm{BnCu}(\mathrm{CN}) \mathrm{MgCl} \cdot 2 \mathrm{LiCl}$ (4 equiv.) in THF at $-78^{\circ} \mathrm{C}$ for 30 min afforded the L,L-type $(2 R, 5 S)$ isostere, Mts-L-Val- $\psi[(E)$-CH=CH $]-\mathrm{L}-\mathrm{Phe}-\mathrm{OMe}, 57$ in $75 \%$ yield as shown in Scheme 4. The most important factor of the MSA-mediated ring-opening reactions is the inversion of configuration at the $\mathrm{C}-\gamma$ carbon via an $\mathrm{S}_{\mathrm{N}} 2$ mechanism. Thus, cis-(E) enoates lead to syn-(E)-mesyl esters, which are converted into L,D-type isosteres upon treatment with organocopper reagents. On the other hand, $c i s-(E)$-enoates themselves produce l,L-type isosteres with organocopper reagents. In a comparative experiment, the trans-( $E$ )-enoate 14 was treated with MSA to afford the anti- $(E)$-mesyl compound 15 , which was converted into the l,L-type isostere 57 with the organocopper reagent in $89 \%$ yield based on $\mathbf{1 4}$. In contrast, treatment of the trans-( $E$ )-enoate $\mathbf{1 4}$ with the organocopper reagent afforded the L,D-type isostere $\mathbf{5 6}$ in $77 \%$ yield. Taken together, two types of
isosteres were stereoselectively synthesized from either the cisor trans-( $E$ )-enoate.

We evaluated the applicability of this synthetic methodology to diverse aziridine cis- $(E)$-enoates, such as D-amino acidderived aziridines and aziridines bearing other functional groups. In the same manner as described above, the cis- $(E)$ enoate 31, which was derived from D -Phe, afforded the corresponding D,L-type isostere, Mts-D-Phe- $\psi[(E)-\mathrm{CH}=\mathrm{CH}]-$ L-Leu-OMe, 59 or the D,D-type isostere, Mts-D-Phe- $\psi[(E)$ -$\mathrm{CH}=\mathrm{CH}]-\mathrm{D}-\mathrm{Leu}-\mathrm{OMe}, 60$ by treatment with MSA and $\mathrm{Bu}^{i} \mathrm{Cu}(\mathrm{CN}) \mathrm{MgCl} \cdot \mathrm{BF}_{3}$ or $\mathrm{Bu}{ }^{i} \mathrm{Cu}(\mathrm{CN}) \mathrm{MgCl} \cdot 2 \mathrm{LiCl}$, respectively. The benzyl ester-bearing aziridine 36 gave the corresponding L,D-type isostere, Mts-L-Leu- $\psi[(E)-\mathrm{CH}=\mathrm{CH}]$-d-Phe-OBn, 62 or the L,L-type isostere, Mts-L-Leu- $\psi[(E)-\mathrm{CH}=\mathrm{CH}]$-L-Phe-OBn, 63 in a similar manner using MSA and $\mathrm{BnCu}(\mathrm{CN}) \mathrm{MgCl} \cdot \mathrm{BF}_{3}$ or $\mathrm{BnCu}(\mathrm{CN}) \mathrm{MgCl} \cdot 2 \mathrm{LiCl}$, respectively. The cis- $(E)$-enoate 44 derived from L-lysine, which possesses the $N^{\varepsilon}-(\mathrm{Cl}-\mathrm{Z})$-protected amino group and the benzyl ester group, was also converted into the isostere, Mts-L-Lys(Cl-Z)- $\psi[(E)-\mathrm{CH}=\mathrm{CH}]-\mathrm{d}-\mathrm{Ala}-\mathrm{OBn}$, 65 or Mts-L-Lys(Cl-Z)- $\psi[(E)-\mathrm{CH}=\mathrm{CH}]-\mathrm{L}-\mathrm{Ala}-\mathrm{OBn}, 66$ by treatment with MSA and $\mathrm{MeCu}(\mathrm{CN}) \mathrm{Li} \cdot \mathrm{LiBr} \cdot \mathrm{BF}_{3}$ or $\mathrm{MeCu}(\mathrm{CN}) \mathrm{Li}$ $\mathrm{LiBr} \cdot 2 \mathrm{LiCl}$, respectively. The cis- $(E)$-enamide $\mathbf{5 4}$ derived from L-serine, which possesses the benzyl ether group and the $N$ methyl amide group, afforded the corresponding amide-type isostere, $\mathrm{Mts}-\mathrm{L}-\mathrm{Ser}(O-\mathrm{Bn})-\psi[(E)-\mathrm{CH}=\mathrm{CH}]-\mathrm{d}-\mathrm{Ala}-\mathrm{NHMe}, \mathbf{6 8}$ or Mts-L-Ser $(O-\mathrm{Bn})-\psi[(E)-\mathrm{CH}=\mathrm{CH}]-\mathrm{L}-\mathrm{Ala}-\mathrm{NHMe}, 69$ by treatment with MSA and $\mathrm{MeCu}(\mathrm{CN}) \mathrm{Li} \cdot \mathrm{LiBr} \cdot \mathrm{BF}_{3}$ or $\mathrm{MeCu}(\mathrm{CN}) \mathrm{Li} \cdot$ $\mathrm{LiBr} \cdot 2 \mathrm{LiCl}$, respectively. These results suggest that this synthetic method is widely applicable to various aziridinyl cis-(E)enoates and enamides. The $(E)$-geometry of the double bond in the obtained isosteres $56,57,59,60,62,63,65,66,68$ and 69 was assigned on the basis of the coupling constant of the two olefinic protons by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analyses. The absolute configuration of the $\alpha$-alkylated carbon centers in the above isosteres was well characterized by circular dichroism (CD) measurements. ${ }^{5,6}$

Synthesis of a key intermediate compound for the preparation of
sphingosines using the ring-opening reaction with TFA
The sphingosines are important constituents of cell membranes, which participate in cell recognition phenomena such as growth, differentiation and immune responses. The sphingosines 72 and 73 are long-chain amino alcohols, and there have been many

reports on their syntheses. ${ }^{106,14}$ One important factor in the asymmetric synthesis of D-erythro- and L-threo-sphingosine 72 and 73 is the stereocontrol in the preparation of the 1,2 -amino alcohol. We investigated the feasibility of the stereocontrolled preparation of a key intermediate compound for the sphingosine synthesis using the TFA-mediated ring-opening reaction of a $\beta$-aziridinyl $\alpha, \beta$-enoate. Exposure of the enoate 55 to TFA at rt for 15 h afforded $\delta$-aminated $\gamma$-trifluoroacetoxy $\alpha, \beta$-enoate 70 by the regiospecific $\mathrm{S}_{\mathrm{N}} 2$ ring-opening reaction. The following hydrolysis of 70 yielded the $\delta$-aminated $\gamma$-hydroxy $\alpha, \beta$-enoate 71 in $71 \%$ yield based on 55 (Scheme 5). The amino alcohol 71 is a key intermediate compound for the l-threo-sphingosine 73 synthesis, and can be also converted into D-erythro-sphingosine 72 by suitable replacement of the $\mathrm{N}^{a}$-protecting group and inversion of stereochemistry of the $\gamma$-hydroxy group using the Mitsunobu reaction. ${ }^{13}$ This result suggests that the TFA-mediated ring-opening reaction is useful for the convenient synthesis of the diastereomerically pure $\delta$-aminated

$\gamma$-hydroxy $\alpha, \beta$-enoates as the key intermediates for several bioactive compounds.

In conclusion, regio- and stereo-specific ring-opening reactions of $N$-Mts-protected aziridines bearing $\alpha, \beta$-unsaturated esters [cis-(E)- and trans-(E)-isomers] by MSA or TFA have been found. The MSA-mediated ring-opening reactions provide a useful approach to the stereoselective synthesis of both L,L-type (or D,D-type) and L,D-type (or D,L-type) ( $E$ )-alkene
dipeptide isosteres from a single substrate of either a $\gamma, \delta$-cis- or -trans- $\gamma, \delta$-epimino ( $E$ )- $\alpha, \beta$-unsaturated ester. L,D-Type and D,Ltype ( $E$ )-alkene dipeptide isosteres are also of comparable use to L,L-type and D,D-type isosteres in the field of medicinal chemistry. $\gamma, \delta$-Epimino $\alpha, \beta$-unsaturated esters can be easily prepared as a mixture of the cis- $(E)-$, cis- $(Z)$-, trans- $(E)$ - and trans-( $Z$ )-isomers from the corresponding chiral amino aldehydes. $\operatorname{Pd}(0)$-catalyzed equilibration reactions of various stereomers of $\gamma, \delta$-epimino $\alpha, \beta$-enoates could afford predominantly cis- $(E)$-isomers in high yields. ${ }^{4}$ Upon treatment with organocopper reagents, these would exclusively provide L,L-type (or D,D-type) ( $E$ )-alkene isosteres. Based on the above results, brief MSA treatment of cis- $(E)-\gamma, \delta$-epimino $\alpha, \beta$-unsaturated esters, gives $\gamma, \delta$-syn- $\delta$-aminated $\gamma$-mesyloxy ( $E$ )- $\alpha, \beta$-enoates, which can be converted into L,D-type (or D,L-type) ( $E$ )-alkene isosteres via organocopper- $\mathrm{BF}_{3}$-mediated anti- $\mathrm{S}_{\mathrm{N}} 2^{\prime}$ reactions. Taken together, the completely stereocontrolled synthetic process for L,L-type, L,D-type, D,D-type and D,L-type ( $E$ )-alkene dipeptide isosteres starting from L -amino acid or D -amino acid has been established. Furthermore, the TFA-mediated ringopening reactions of $c i s-(E)$-enoates have provided a useful methodology for the stereoselective synthesis of $\delta$-aminated $\gamma$-hydroxy $\alpha, \beta$-enoates such as a key intermediate compound for the sphingosine synthesis. Many of the existing method-
ologies for the synthesis of sphingosines are accompanied by difficulties in 1,2-amino alcohol stereocontrol. ${ }^{100,14}$ However, our procedure lacks such stereocontrol problems, since TFAmediated stereoselective ring-opening reactions of $\beta$-aziridinyl $\alpha, \beta$-enoates are unequivocally related to the stereochemistry of 1,2-amino alcohol construction.

${ }^{1} \mathrm{H}$ NMR spectra were recorded using a JEOL EX-270 or a Bruker AC 300 spectrometer at 270 or $300 \mathrm{MHz}{ }^{1} \mathrm{H}$ frequency for samples in $\mathrm{CDCl}_{3}$. Chemical shifts are reported in parts per million downfield from internal tetramethylsilane. Nominal (LRMS) and exact mass (HRMS) spectra were recorded on a JEOL JMS-01SG-2 or JMS-HX/HX 110A mass spectrometer. Optical rotations were measured in $\mathrm{CHCl}_{3}$ with a JASCO DIP360 digital polarimeter. CD spectra were measured in isooctane (2,2,4-trimethylpentane) at $24^{\circ} \mathrm{C}$ with a JASCO J-720 spectropolarimeter. IR spectra were obtained on a Shimadzu Model IR-400 spectrometer. Mps were measured by a hot stage melting point apparatus and are uncorrected. For flash chromatography, silica gel 60 H (silica gel for thin-layer chromatography, Merck) and Wakogel C-200 (silica gel for column chromatography) were employed.

DIBAL in $n$-hexane ( $73.8 \mathrm{~cm}^{3}, 68.6 \mathrm{mmol} ; 0.93 \mathrm{~mol} \mathrm{dm}^{-3}$ solution) was added dropwise to a stirred solution of the ester 24 $(5 \mathrm{~g}, 17.9 \mathrm{mmol})$ in $20 \mathrm{~cm}^{3}$ of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at $-78^{\circ} \mathrm{C}$ under argon. The mixture was allowed to warm to rt and stirring was continued for 3 h . The mixture was recooled to $-78^{\circ} \mathrm{C}$, and saturated aq. $\mathrm{NH}_{4} \mathrm{Cl}\left(10 \mathrm{~cm}^{3}\right)$ was added dropwise with vigorous stirring. The inorganic salts were removed by filtration through Celite. The filtrate was extracted with EtOAc, and the extract was washed with water and dried over $\mathrm{MgSO}_{4}$. The usual work-up and flash chromatography over silica gel with $n$-hexane-EtOAc (2:1) gave a crystalline mass. To a stirred solution of $N^{\varepsilon}-(\mathrm{Cl}-\mathrm{Z})$-protected $(S)$-lysine 37 ( 3 g , $9.53 \mathrm{mmol})$ and $\mathrm{Et}_{3} \mathrm{~N}\left(3.31 \mathrm{~cm}^{3}, 23.8 \mathrm{mmol}\right)$ in $\mathrm{H}_{2} \mathrm{O}\left(10 \mathrm{~cm}^{3}\right)$ at $0^{\circ} \mathrm{C}$ was added $2.50 \mathrm{~g}(11.4 \mathrm{mmol})$ of $\mathrm{Mts}-\mathrm{Cl}$. After being stirred for 15 h , the mixture was made acidic with saturated aq. citric acid and extracted with EtOAc and the extract was washed with water and dried over $\mathrm{MgSO}_{4}$ to give a crude $N^{\alpha}$ and $N^{\varepsilon}$-protected lysine as a colourless oil. To a stirred solution of the above $N^{\alpha}$ - and $N^{\varepsilon}$-protected lysine in DMF $\left(10 \mathrm{~cm}^{3}\right)$ at $0^{\circ} \mathrm{C}$ were added $\mathrm{HOBt}(1.61 \mathrm{~g}, 10.5 \mathrm{mmol}), \mathrm{WSCD}\left(1.82 \mathrm{~cm}^{3}\right.$, 10.5 mmol ) and $\mathrm{N}, \mathrm{O}$-dimethylhydroxylamine hydrochloride $(1.02 \mathrm{~g}, 10.5 \mathrm{mmol})$. After being stirred at rt for 15 h , the solution was concentrated under reduced pressure and extracted with EtOAc. The extract was washed successively with $5 \%$ citric acid, water, $5 \% \mathrm{NaHCO}_{3}$ and water, and dried over $\mathrm{MgSO}_{4}$.

Usual work-up and flash chromatography over silica gel with $n$-hexane-EtOAc (3:1) gave $3.78 \mathrm{~g}(7.00 \mathrm{mmol}, 74 \%)$ of the title compound $\mathbf{3 8}$ as a colourless crystalline mass, mp 111$113{ }^{\circ} \mathrm{C}$ [from $n$-hexane- $\mathrm{Et}_{2} \mathrm{O}$ (5:1)] (Found: C, 55.64; H, 6.51; N , 7.58. $\mathrm{C}_{25} \mathrm{H}_{34} \mathrm{ClN}_{3} \mathrm{O}_{6} \mathrm{~S}$ requires C , $55.66 ; \mathrm{H}, 6.35 ; \mathrm{N}$, $7.78 \%)$; $[a]_{\mathrm{D}}^{21}+14.7\left(c 1.39\right.$ in $\left.\mathrm{CHCl}_{3}\right) ; \delta_{\mathrm{H}}\left(270 \mathrm{MHz} ; \mathrm{CDCl}_{3}\right)$ $1.30\left(4 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 1.57\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 2.27(3 \mathrm{H}, \mathrm{s}, \mathrm{CMe})$, 2.65 ( $6 \mathrm{H}, \mathrm{s}, \mathrm{CMe}$ ), 2.98 ( $3 \mathrm{H}, \mathrm{s}, \mathrm{NMe}$ ), $3.13\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right.$ ), $3.51(3 \mathrm{H}, \mathrm{s}, \mathrm{OMe}), 4.16(1 \mathrm{H}, \mathrm{m}, 2-\mathrm{H}), 4.85(1 \mathrm{H}, \mathrm{m}, \mathrm{NH})$, $5.21\left(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2}\right), 5.59(1 \mathrm{H}, \mathrm{d}, J 9.6, \mathrm{NH}), 6.92(2 \mathrm{H}, \mathrm{s}$, $\mathrm{ArH})$ and $7.24-7.45(4 \mathrm{H}, \mathrm{m}, \mathrm{ArH}) ; m / z$ (FAB-LRMS) 540 $\left(\mathrm{MH}^{+}\right), 496,398,353$ (base peak), 309, 252, 208, 183, 127, $125,119,91$ and 84 .

By use of a procedure identical with that described for the preparation of $\mathbf{3 0}$ from 29 , the mixture of the alcohols 50 and $51(760 \mathrm{mg}, 1.95 \mathrm{mmol})$ was converted into 640 mg ( $1.72 \mathrm{mmol}, 88 \%$ ) of the diastereomixture of the vinylaziridines 52 and 53 as a colourless oil [Found (FAB): $(\mathrm{M}+\mathrm{H})^{+}$, 372.1626. $\mathrm{C}_{21} \mathrm{H}_{25} \mathrm{NO}_{3} \mathrm{~S}$ requires $\left.M+\mathrm{H}, \quad 372.1634\right] ; \mathrm{m} / \mathrm{z}$ (FAB-LRMS) $372\left(\mathrm{MH}^{+}\right), 302,264$ (base peak), 188, 183, 119 and 91.
(2E,4R,5R)-6-Benzyloxy- $N$-methyl-4,5-[(2,4,6-trimethylphenyl-sulfonyl)epimino]hex-2-enamide 54

By use of a procedure identical with that described for the preparation of the corresponding aldehyde from 30, the mixture of the vinylaziridines 52 and $53(580 \mathrm{mg}, 1.56 \mathrm{mmol})$ was converted into the crude diastereomixture of the corresponding aldehydes. To a stirred solution of $\mathrm{LiCl}(159 \mathrm{mg}, 3.75$ mmol) in $2 \mathrm{~cm}^{3}$ of $\mathrm{CH}_{3} \mathrm{CN}$ at $0^{\circ} \mathrm{C}$ was added via syringe DIPEA ( $0.652 \mathrm{~cm}^{3}, 3.75 \mathrm{mmol}$ ) and a $\mathrm{CH}_{3} \mathrm{CN}$ solution $\left(5 \mathrm{~cm}^{3}\right)$ of diethoxphosphoryl- $N$-methylacetamide (791 mg, 3.75 mmol ), which was prepared by treatment of ethyl diethyloxyphosphorylacetate with methylamine ( 5 equiv.) in MeOH , and the mixture was stirred at this temperature for 30 min . To the mixture at $0^{\circ} \mathrm{C}$ was added dropwise a solution of the above crude aldehydes in $\mathrm{CH}_{3} \mathrm{CN}\left(3 \mathrm{~cm}^{3}\right)$, and the stirring was continued at rt for 12 h . The mixture was concentrated under reduced pressure to leave a semisolid, which was extracted with EtOAc and the extract was washed successively with water, 1 $\mathrm{mol} \mathrm{dm}{ }^{-3} \mathrm{HCl}$, water, saturated aq. $\mathrm{NaHCO}_{3}$ and water, and dried over $\mathrm{MgSO}_{4}$. Concentration under reduced pressure gave a residue, which was purified by flash chromatography over silica gel with $n$-hexane- $\operatorname{EtOAc}(5: 1)$ to give a mixture of the enamide 54 and its diastereoisomer.
