Triisopropylamine $\mathbf{1 a}$ and $\mathrm{S}_{2} \mathrm{Cl}_{2}$, in the presence of DABCO and formic acid, give the bicyclic amine $\mathbf{2 a}$, and its $N$-dealkylated product 3, rather than the tricyclic bisdithiolothiazine system $\mathbf{7}$ produced by Hünig's base $\mathbf{1 b}$. However, when $\mathrm{S}_{2} \mathrm{Cl}_{2}$ is in molar excess over DABCO, Hünig's base and related $N$-alkyldiisopropylamines $\mathbf{1 c}-\mathbf{g}$ also give the analogous bicyclic compounds $\mathbf{2 b -} \mathbf{g}$ together with the tricyclic compounds $\mathbf{7 b}-\mathbf{g}$. The $N$-benzyl compound $\mathbf{2 c}$ is debenzylated quantitatively to the secondary amine $\mathbf{3}$ by sulfuric acid. X-Ray crystallography of $N, N$-bis(dithiolyl)ethylamine $\mathbf{2 b}$ shows the two dithiole rings to be steeply inclined to each other $\left(85^{\circ}\right)$ and the geometry at nitrogen to be slightly pyramidal. The crystal packing is dominated by $\mathrm{S} \cdots \mathrm{O}$ electrostatic and weak $\mathrm{C}=\mathrm{O} \cdots \mathrm{Cl}$ charge-transfer interactions.
$N$-Ethyldiisopropylamine (Hünig's base) is a hindered nonnucleophilic base, commonly used as a deprotonating reagent in many organic reactions. In contrast to its generally assumed inertness, we have shown that it reacts with disulfur dichloride, $\mathrm{S}_{2} \mathrm{Cl}_{2}$, under very mild conditions to give bis $[1,2]$ dithiolo $[1,4]$ thiazines, ${ }^{1}$ bis $[1,2]$ dithiolopyrroles, ${ }^{2}$ and a dihydro [1,2]dithiolo[ 1,4$]$ thiazine, ${ }^{3}$ in one-pot reactions. Under carefully controlled reaction conditions each of these heterocyclic systems can be obtained selectively. ${ }^{4}$ Only the isopropyl groups react with $\mathrm{S}_{2} \mathrm{Cl}_{2}$, the ethyl group being inert. N -(2-Chloroethyl)diisopropylamine reacts similarly, ${ }^{3}$ and even $N$-benzyldiisopropylamine reacts in the same way to give the $N$-benzyl bisdithiolothiazines and pyrroles and hence, by debenzylation, the parent $N-\mathrm{H}$ compounds. ${ }^{5}$ To explore the limits of the reaction we have now included a third isopropyl group in the starting amine, subjecting the highly crowded triisopropylamine to the action of $\mathrm{S}_{2} \mathrm{Cl}_{2}$ and have obtained the first member of a new class of stable bis(1,2-dithiol-4-yl)amines. Furthermore we report how these bicyclic bis(dithiolyl)amines can be produced from other $N$-alkyldiisopropylamines in one-pot reactions with $\mathrm{S}_{2} \mathrm{Cl}_{2}$ under appropriate conditions.

Triisopropylamine ${ }^{6}$ 1a was treated with $\mathrm{S}_{2} \mathrm{Cl}_{2}$ (15 equiv.) and 1,4-diazabicyclo[2.2.2]octane (DABCO) (12 equiv.) in 1,2dichloroethane for 3 d at room temperature. Formic acid (30 equiv.) was then added and the mixture heated under reflux for 1.5 h since this treatment gives cleaner reactions by facilitating the hydrolysis of intermediate 3 -chlorodithiolium salts to dithiol-3-ones. ${ }^{4}$ Products 2a, orange solid, $\mathrm{C}_{9} \mathrm{H}_{7} \mathrm{Cl}_{2} \mathrm{NO}_{2} \mathrm{~S}_{4}, \mathrm{mp}$ $138-140{ }^{\circ} \mathrm{C}(12 \%)$ and 3 , orange solid, $\mathrm{C}_{6} \mathrm{HCl}_{2} \mathrm{NO}_{2} \mathrm{~S}_{4}, \mathrm{mp} 144-$ $145^{\circ} \mathrm{C}(6 \%)$ were obtained after chromatography (Scheme 1). Structures 2a and $\mathbf{3}$ were elucidated from mass spectrometry, HRMS, ${ }^{1} \mathrm{H}-$ and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ and IR spectroscopy. When triisopropylamine 1a was treated with an excess of $\mathrm{S}_{2} \mathrm{Cl}_{2}$ and DABCO in equimolecular proportions ( 16 equiv.), followed by treatment with formic acid, only $\mathbf{3}$ was isolated, in very small amounts; without the formic acid treatment no pure products

Scheme 1
could be isolated. It appears that for this amine an excess of $\mathrm{S}_{2} \mathrm{Cl}_{2}$ over DABCO is needed to furnish stable products. Under these conditions triisopropylamine starts to react like Hünig's base, ${ }^{4}$ following the sequence of dehydrogenation, displacement of chlorine from $\mathrm{S}_{2} \mathrm{Cl}_{2}$ and chlorination, up to formation of the intermediate 4 (cf. ref. 4) (Scheme 2). The next step in our proposed mechanism would be cyclization of $\mathbf{4}$ to $5,{ }^{4}$ but if we assume that these tricyclic dithiolium salts are highly delocalised and hence near-planar, the $N$-isopropyl intermediate 5 will be markedly more crowded than the $N$-ethyl analogue. Computational modelling ${ }^{7}$ shows that the planar structure 5 is sterically forbidden. Instead of ring closure to $\mathbf{5 , 4}$ could be chlorinated further by the excess of $\mathrm{S}_{2} \mathrm{Cl}_{2}$ to give $\mathbf{6}$ which would be converted by formic acid into the bicyclic $N$-isopropyl compound 2a which, in turn, could be slowly dealkylated by the hot acid to give the secondary amine 3 (Scheme 2). Interestingly, there was no sign that the remaining isopropyl group in 2a had reacted with $\mathrm{S}_{2} \mathrm{Cl}_{2}$ to give a third 1,2-dithiole ring. This could be a consequence of the electron-withdrawing effect of the two dichlorodithiolium rings (or the derived chlorodithiolone rings) which would suppress the oxidation of the third $N$-isopropyl group to the iminium ion (cf. Scheme 2). For the same reason one N -acetyl or N -cyano group protects diisopropylamine from reaction with $\mathrm{S}_{2} \mathrm{Cl}_{2}$ under the same conditions. ${ }^{4}$

We have proposed in Scheme 2 that bis-dithiolium salt $\mathbf{4}$ is the key intermediate which is diverted from further cyclisation by ring chlorination when DABCO is in deficiency with respect

$3 a$

## Scheme 2

to disulfur dichloride. If this assumption is correct a similar diversion of the reaction of other $N$-alkyldiisopropylamines might also be observed under the same conditions to give hitherto undetected bicyclic products analogous to $\mathbf{2 a}$, and we now find this to be the case. Thus, $N$-ethyldiisopropylamine 1b (1 equiv.) was treated with $\mathrm{S}_{2} \mathrm{Cl}_{2}$ (10 equiv.) and DABCO (6 equiv.) in 1,2-dichloroethane for 3 d at room temperature. Formic acid ( 20 equiv.) was then added and the mixture heated under reflux for 1.5 h . Chromatography afforded the bicyclic product $\mathbf{2 b}$, yellow solid, $\mathrm{C}_{8} \mathrm{H}_{5} \mathrm{Cl}_{2} \mathrm{NO}_{2} \mathrm{~S}_{4}, \mathrm{mp} 132-133{ }^{\circ} \mathrm{C}(19 \%)$ and the previously reported tricyclic product $7 \mathbf{b}^{4}(10 \%)$ (Scheme 3). The structure of $\mathbf{2 b}$ was determined from mass spectrometry, HRMS, ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR and IR spectroscopy and was confirmed by X-ray diffraction (see below). Analogous treatment of $N$-benzyldiisopropylamine 1c with $\mathrm{S}_{2} \mathrm{Cl}_{2}$ (10 equiv.) and DABCO (6 equiv.) in 1,2-dichloroethane for 3 d at room temperature followed by addition of formic acid (20 equiv.) and heating under reflux for 1 h gave $\mathbf{2 c}$, yellow crystals, $\mathrm{mp} 164-165^{\circ} \mathrm{C}(15 \%)$ in addition to the previously reported compound $\mathbf{7 c}{ }^{5}$ ( $27 \%$ ) (Scheme 3). The structure of $\mathbf{2 c}$ was fully supported by its spectroscopic properties. Treatment of a dilute solution of the $N$-benzyl compound $2 \mathbf{2}$ in dichloromethane with concentrated sulfuric acid at $5-10^{\circ} \mathrm{C}$ for 30 min gave a quantitative yield of the debenzylated compound 3 , identical with that from triisopropylamine 1a.

Similarly, treatment of $N$-(2-chloroethyl)diisopropylamine 1d with $\mathrm{S}_{2} \mathrm{Cl}_{2}$, DABCO and formic acid (20 equiv.) as shown in Table 1 gave the bicyclic compound 2d, yellow crystals, $\mathrm{C}_{8} \mathrm{H}_{4} \mathrm{Cl}_{3} \mathrm{NO}_{2} \mathrm{~S}_{4}, \mathrm{mp} 97-98^{\circ} \mathrm{C}(7 \%)$ in addition to tricyclic compound $7 \mathbf{d}^{3}(20 \%)$. In the same way the $N$-phenylthioethyl 1e, phthalimidoethyl 1f, and tetrachlorophthalimidoethyl $\mathbf{1 g}$ derivatives of diisopropylamine, which were prepared from 1d, ${ }^{8}$ were converted into the analogous bicyclic (ca. 20\% yield) and

Fig. 1 The molecular structure of $\mathbf{2 b}$. Selected bond lengths $(\AA)$ are: $\mathrm{S}(1)-\mathrm{C}(8 \mathrm{~A}) 1.735(4), \mathrm{S}(1)-\mathrm{S}(2)$ 2.050(2), S(2)-C(3) 1.792(4), C(3)-O(3) $1.208(5), \mathrm{C}(3)-\mathrm{C}(3 \mathrm{~A}) 1.456(6), \mathrm{C}(3 \mathrm{~A})-\mathrm{C}(8 \mathrm{~A}) 1.347(6), \mathrm{C}(3 \mathrm{~A})-\mathrm{N}(4)$ $1.408(5), \mathrm{N}(4)-\mathrm{C}(4 \mathrm{~A}) 1.405(5), \mathrm{N}(4)-\mathrm{C}(9) 1.472(5), \mathrm{C}(4 \mathrm{~A})-\mathrm{C}(7 \mathrm{~A})$ $1.347(6), \mathrm{C}(4 \mathrm{~A})-\mathrm{C}(5) 1.468(5), \mathrm{C}(5)-\mathrm{O}(5) 1.204(5), \mathrm{C}(5)-\mathrm{S}(6) 1.787(4)$, $\mathrm{S}(6)-\mathrm{S}(7) 2.046(2), \mathrm{S}(7)-\mathrm{C}(7 \mathrm{~A}) 1.727(4), \mathrm{C}(7 \mathrm{~A})-\mathrm{Cl}(7) 1.706(4), \mathrm{C}(8 \mathrm{~A})-$ $\mathrm{Cl}(8) 1.701(4)$.

Scheme 3
tricyclic (ca. 15\% yield) compounds (Scheme 3 and Table 1). These results are all explicable by the mechanism proposed in Scheme 2 where the bisdithiolium intermediate (cf. 4) is either chlorinated further or (except for $N$-isopropyl) cyclised to a 1,4-thiazine.

The complex reactions of $N$-alkyldiisopropylamines with $\mathrm{S}_{2} \mathrm{Cl}_{2}$ provide new routes to novel heterocyclic structures by diversion of intermediates on the way to complete sulfuration of both isopropyl groups. We have now shown that chlorination by $\mathrm{S}_{2} \mathrm{Cl}_{2}$ and a deficiency of DABCO , and hydrolysis by formic acid, of these readily available tertiary amines give $N, N$-bis(1,2-dithiol-4-yl)amine $\mathbf{3}$ and its $N$-alkyl derivatives $\mathbf{2 b}-\mathbf{g}$ in one-pot, though low-yielding, reactions. Whilst 5-amino derivatives of 1,2-dithiol-3-ones and -thiones are readily available by displacement of chlorine from the activated 5-position, ${ }^{9} 4$-amino isomers like $\mathbf{2}$ and $\mathbf{3}$ appear to be very rare. ${ }^{\mathbf{1 0}}$

The X-ray analysis of $\mathbf{2 b}$ confirmed the bisdithiole nature of the compound (Fig. 1), the two dithiole rings being inclined almost orthogonally ( $85^{\circ}$ between their mean planes), this geometric arrangement being produced by torsional twists of 59 and $61^{\circ}$ about the $\mathrm{C}(3 \mathrm{~A})-\mathrm{N}(4)$ and $\mathrm{N}(4)-\mathrm{C}(4 \mathrm{~A})$ bonds respectively. The geometry at the nitrogen centre is slightly pyramidalized with $N(4)$ lying $0.16 \AA$ out of the $C(3 A)-C(4 A)-C(9)$ plane-the dithiole rings are inclined by $69[C(3 A)]$ and $50^{\circ}$ $[\mathrm{C}(4 \mathrm{~A})]$ to this plane. The pattern of bonding within each ring reflects the formal double bond character of the $C(3 A)-C(8 A)$

Table 1 Reaction of amines with $\mathrm{S}_{2} \mathrm{Cl}_{2}, \mathrm{DABCO}$ and formic acid

| Amine | Reagents |  |  | Formic acid/ mmol | Reflux time/min | Yields of products (\%) |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Amine/ mmol | $\begin{aligned} & \mathrm{S}_{2} \mathrm{Cl}_{2} / \\ & \mathrm{mmol} \end{aligned}$ | DABCO/ <br> mmol |  |  |  |  |  |  |
| 1a | 5 | 75 | 60 | 150 | 90 | 2a | 12 | 3 | 6 |
| 1b | 5 | 50 | 30 | 100 | 60 | 2b | 19 | $7{ }^{4}$ | 10 |
| 1c | 5 | 50 | 30 | 100 | 60 | 2 c | 15 | $7{ }^{5}$ | 20 |
| 1d | 5 | 50 | 25 | 100 | 45 | 2 d | 7 | $7{ }^{3}$ | 20 |

${ }^{a}$ Tetramethylammonium chloride ( 30 mg ) was added to the reaction mixture.

Fig. 2 Part of one of the loosely-linked chains of molecules present in the crystals of $\mathbf{2 b}$. The intrachain $\mathrm{S} \cdots \mathrm{O}$ contacts are: a) 3.12, b) 3.06, c) 3.08 and d) $3.08 \AA$.
and $\mathrm{C}(4 \mathrm{~A})-\mathrm{C}(7 \mathrm{~A})$ linkages [both $1.347(6) \AA$ ], though these distances are noticeably greater than that for an isolated $\mathrm{C}=\mathrm{C}$ and indicate a degree of delocalisation within the ring system. Structural data for 1,2 -dithiol-3-one ring systems are sparse and, with the exception of the fused ring systems that we have described previously, ${ }^{4,5}$ the current release of the Cambridge Crystallographic Database (October 1998) contains only two other examples ${ }^{11,12}$ of pendant 1,2-dithiol-3-one containing systems. Of these, the closer analogue is 4-methyl-5-(pyrazin-2yl )-3 H -1,2-dithiol-3-one where the pattern of bonding in the dithiole ring does not differ significantly from that observed here.

The packing of the molecules (Fig. 2) is dominated by electrostatic $\mathrm{O} \cdots \mathrm{S}$ interactions (ranging between 3.06 and $3.12 \AA$ ) and parallel stacking of the dithiole rings of symmetry related molecules; the mean interplanar separations are $3.73[\mathrm{C}(3 \mathrm{~A})$ ring to $\mathrm{C}(3 \mathrm{~A})$ ring] and $3.85 \AA[\mathrm{C}(4 \mathrm{~A})$ ring to $\mathrm{C}(4 \mathrm{~A})$ ring]. These interactions combine to form rather elegant twisted chains that extend in the crystallographic $c$ direction. Adjacent $C_{\mathrm{i}}$-related chains are oriented such that the carbonyl groups in one chain are directed towards the chlorine atoms in the next and vice versa (Fig. 3). The $\mathrm{O} \cdots \mathrm{Cl}$ distances, 3.03 and $3.04 \AA$, are significantly less than the sum of their van der Waals radii (ca. $3.2 \AA$ ) and clearly indicate some form of intermolecular interaction. If we ignore the possibility of significant intramolecular electron-transfer between the two dithiole rings, then the 4 -amino- 5 -chloro-1,2-dithiole moiety can be represented by the resonance forms A-C in Scheme 4, with a minor contribution from $\mathbf{D}$. The oxygen atom carries a partial negative charge,

Fig. 3 The $\mathrm{C}=\mathrm{O} \cdots \mathrm{Cl}$ linking of adjacent centrosymmetrically related chains. The $\mathrm{O} \cdots \mathrm{Cl}$ distances are: e) 3.03 and f) 3.04 A .

Scheme 4
explaining the 3 -centre $\mathrm{O} \cdots \mathrm{S}$ interactions a to d in Fig. 2, which are clearly electrostatic. If a small positive charge were induced on the chlorine atom, as in contribution $\mathbf{D}$, then the intermolecular $\mathrm{O} \cdots \mathrm{Cl}$ interactions e and f (Fig. 3) could also be electrostatic in nature, but the observed bond lengths do not indicate any marked shortening of either the $\mathrm{C}-\mathrm{Cl}$ or the $\mathrm{C}(3 \mathrm{~A})-\mathrm{C}(3)[\mathrm{C}(4 \mathrm{~A})-\mathrm{C}(5)]$ bond lengths. A survey of the literature reveals that short intermolecular $\mathrm{C}=\mathrm{O} \cdots \mathrm{Cl}$ contacts are relatively commonplace ( 159 examples in the range 2.86$3.20 \AA$ ), though infrequently commented upon. However, two particular examples, in the structure of 2,3-dichlorobenzo1,4 -quinone, ${ }^{13}$ and perhaps more relevantly in that of 5 -chloropyrimidin-2-one, ${ }^{14}$ this type of interaction has been attributed to "donor-acceptor" and "charge transfer" bonding
respectively. Examples of strong interactions of this type have been discussed in a review by Hassel and Rømming ${ }^{15}$ and are considered to involve a lone pair on the carbonyl and the d-orbitals of the halogen. We think it likely that the $\mathrm{C}=\mathrm{O} \cdots \mathrm{Cl}$ contacts in the structure of $\mathbf{2 b}$ are probably examples of weak interactions of this type.

## Experimental

Melting points were determined on a Kofler hot-stage apparatus and are uncorrected. IR spectra were recorded on a Bruker Vector 200 A instrument in KBr pellets. ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker DRX 400 in $\mathrm{CDCl}_{3}$ or $d_{5}$-pyridine solution. CH groups were distinguished by DEPT experiments. $J$ values are given in Hz . Mass spectra were recorded on VG7070E and VG-AutoSpec instruments using electron impact ionisation. Light petroleum refers to the fraction bp $40-60^{\circ} \mathrm{C}$.

## General procedure for the preparation of $\mathrm{N}, \mathrm{N}$-bis( 5 -chloro-3-oxo-1,2-dithiol-4-yl)alkylamines 2a-g

Disulfur dichloride was added dropwise to a stirred solution of $N$-alkyldiisopropylamine 1a-g and DABCO dissolved in 1,2dichloroethane $(150 \mathrm{ml})$ at $-40^{\circ} \mathrm{C}$. The mixture was stirred for 15 min at $-40^{\circ} \mathrm{C}$, then for 3 days at room temperature. Formic acid was then added dropwise at $5^{\circ} \mathrm{C}$ and the mixture was refluxed for 45 min to 1.5 h . The reaction mixture was filtered through Celite and the solvent was removed in a rotary evaporator. Medium pressure liquid chromatography (MPLC) (silica gel Merck 60 , light petroleum to $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) of the residue afforded products $2 \mathbf{a}-\mathbf{g}$, in addition to the previously reported products $\mathbf{7 b}-\mathbf{g}$. The reaction conditions and yields of products are given in Table 1.
