#### Abstract

Overall 5-endo-trig iodocyclisations of all isomers of the 2-alkenylcyclopentan-1-ols and -cyclohexan-1-ols 11, 12, $\mathbf{1 4}$ and $\mathbf{1 6}$ have been examined. Only in the cases of the trans-alkenylcyclopentanols 11a and 12a are the reactions either unsuccessful or low yielding, by reason of formation of a relatively strained trans-fused $5 / 5$ ring system. In contrast, iodocyclisations of cis-alkenylcyclopentanols work well but only show useful stereoselection in the case of the cis-$(Z)$-alkenylcyclopentanol 16a. All examples involving the cyclohexanols 14 and 16 are high yielding and generally lead to single isomers of perhydro-3-iodobenzofurans 18, 20, 23 and 26. Transition state conformations are proposed which account for these observations and which should be useful in applying this type of cyclisation to related substrates.

During the past few years, overall 5 -endo-trig cyclisations have become established as synthetically useful and often highly stereoselective processes for the elaboration of saturated five-membered heterocycles. ${ }^{1-3}$ In the case of the ( $E$ )-homoallylic alcohols 1, such cyclisations can be effected by treatment with three equivalents each of iodine and sodium hydrogen carbonate in dry acetonitrile and lead, highly selectively, to the tetrahydrofuran diastereoisomers 2. These conditions are based on those originally developed by Bartlett and co-workers ${ }^{4}$ during their studies of iodolactonization reactions. In the present examples, the use of anhydrous conditions appears to be essential: if water is present, the major products are the iodohydrins derived from the homoallylic alcohols 1. In contrast to the generally rapid cyclisations of the $(E)$-isomers 1, similar reactions of the corresponding ( $Z$ )-isomers are much slower and give poorer yields of the all-cis trisubstituted tetrahydrofurans 3, but again as single diastereoisomers. These observations are consistent with the intermediacy of the chair conformation 4, controlled by the equatorial position of the substituent R ; the poorer cyclisations of the $(Z)$-isomers of alcohols $\mathbf{1}$ are thus explained by the necessarily axial positioning of the alkene substituent Z . We were intrigued by the prospect that this type of cyclisation could be extended to the formation of ring-fused tetrahydrofurans 6 from stereoisomers of the 2-alkenylcycloalkanols $5 .{ }^{5}$ However, at the outset, extrapolation of the transition state model 4 to the more constrained analogues 5 gave unclear indications regarding the prospects for success; while the 1,2-trans-isomers appeared to be very well set up for cyclisation via conformation 7, it was far from clear whether the related cis isomers would undergo cyclisation at all, as the two reacting centres appeared rather distant in the anticipated initial reacting conformation 8. In the event, most of the cyclisations were very successful; herein, we report full details of these findings. ${ }^{6}$

## Results and discussion

The necessary starting materials $\mathbf{1 1}, \mathbf{1 2}, \mathbf{1 4}$ and $\mathbf{1 6}$ were readily prepared from epoxycyclopentane and epoxycyclohexane respectively $[9 ; n=1,2]$ (Scheme 1). Yamaguchi-Hirao alkylation ${ }^{7}$ of lithiohexyne using these electrophiles with boron trifluoride-diethyl ether as the activating species led to good isolated yields of the trans-2-alkynylcycloalkanols $\mathbf{1 0}$. Direct reduction using lithium aluminium hydride in refluxing tetrahydrofuran-toluene ${ }^{8}$ then gave the first pair of precursors, the trans- $(E)$-isomers 11. Lindlar reduction gave the corresponding trans-( $Z$ )-isomers 12, both in excellent yields. The related cis-isomers, $\mathbf{1 4}$ and 16, were accessed by a smooth Mitsunobu inversion ${ }^{9}$ of the initial alkynols 10 using $p$-nitrobenzoic acid as the nucleophile. ${ }^{10}$ Treatment of the

resulting esters $\mathbf{1 3}$ with lithium aluminium hydride, by the foregoing method, both removed the ester group and reduced the alkyne to give the required cis-( $E$ )-alkenylcycloalkanols 14, while saponification of esters $\mathbf{1 3}$ followed by Lindlar reduction of the resulting alkynols $\mathbf{1 5}$ gave the final members of the series, the cis-( $Z$ )-isomers 16.

The central cyclisations were performed under a standard set of conditions, ${ }^{1,4}$ consisting of exposure of the substrates 11, 12, 14 and 16 to three equivalents of iodine in dry acetonitrile containing three equivalents of sodium hydrogen carbonate at $0^{\circ} \mathrm{C}$. The trans- $(E)$-alkenylcyclopentanol 11a underwent rather slow cyclisation and it was only after approximately 48 hours that the starting material has all reacted according to TLC analysis, which indicated the formation of an ominous number of products. A simple aqueous work-up followed by chromatographic separation delivered a single hexahydrocyclopenta[b]furan 17 in $29 \%$ isolated yield, the structure of which was deduced as outlined below. Other products appeared to be the corresponding iodohydrins, presumably formed as water was generated during the cyclisation leading to the bicycle 17, although the addition of drying agents such as molecular sieves or magnesium sulfate failed to improve the yield. On reflection, we realised that this could be regarded as a remarkable result, in that the relatively strained trans-fused $5 / 5$ ring system in 17 had been formed at all. Further, the relative stereochemistry was consistent with a reacting conformation based on that anticipated (7) from initial studies. ${ }^{1}$ This was borne out when the corresponding cyclohexane derivative 11b was similarly exposed to iodine: in this case, cyclisation occurred to give a single perhydrobenzofuran $\mathbf{1 8}$ in essentially quantitative yield in about one hour at $0^{\circ} \mathrm{C}$. This was consistent with the formation of a much less strained trans-fused $6 / 5$ ring system during cyclisation, again via a transition state related to conformation 7. Despite the excellent yield obtained from this cyclisation
we examined a few alternative conditions using substrate 11b. We found that powdered sodium hydroxide could be used as the base, in place of sodium hydrogen carbonate, without reducing the yield. The cyclisation also worked, but slightly less efficiently ( $\sim 80 \%$ isolated yield), in the absence of base; hence, in such favourable examples, competing iodohydrin formation is not especially deleterious although clearly in examples containing more sensitive functionality, exposure to the hydrogen iodide generated during the cyclisation could be a significant drawback. $N$-Iodosuccinimide was also effective as an iodonium source, but cyclisation was some five times slower. Perhaps surprisingly, when either triethylamine or $N, N$-diisopropylethylamine (Hünig's base) was used as the base in place of sodium hydrogen carbonate, no cyclisation was observed even after prolonged exposure to three equivalents of iodine. The requirement of three equivalents of iodine suggests that more complex species than simply iodonium ions are necessary for these and related cyclisations ${ }^{1,3,4}$ and that these are not present when tertiary amines are used as base; in all cases, use of less than three equivalents resulted in incomplete conversion, as had been noted previously. ${ }^{1,3}$ Returning to the original substrates, it was next found that the trans-( $Z$ )-cyclopentanol 12a failed to cyclise to give isomers of the trans-fused system 19, whereas the corresponding cyclohexanol 12b underwent smooth but slow cyclisation, relative to the related trans- $(E)$ isomer 11b, to give the perhydrobenzofuran diastereoisomer 20. Our model work ${ }^{1}$ had revealed that $(Z)$-homoallylic alcohols in general are relatively poor substrates for this type of cyclisation (see above and structure 4). It seems likely therefore that a similar effect applies in these two cases which involve the $(Z)$-isomer of conformation 7. In the case of the cyclopentanol 12a, a combination of this and the additional requirement of formation of a trans-fused $5 / 5$ bicyclic system 19 proved just too much to permit the cyclisation to proceed. That the less strained trans-5/6 bicycle 20 was formed in good yield but at a much slower rate, relative to cyclisation of the corresponding trans- $(E)$-isomer 11b, is probably just a reflection of a higher energy transition state brought about by the pseudoaxial positioning of the butyl side-chain.

We then turned to the corresponding cis-alkenylcycloalkanols $\mathbf{1 4}$ and 16, not certain if these would undergo cyclisation at all, in view of the likely initial conformation 8 . In the event, cyclisations of the cis-(E)-cycloalkanols 14a and 14b

turned out to be somewhat too facile, being both relatively rapid and giving mixtures of products. The cis-fused hexahydrocyclopenta[b]furans $\mathbf{2 1}$ and $\mathbf{2 2}$ were obtained in a $1.25: 1$ ratio, slightly improved by performing the cyclisations at $-78^{\circ} \mathrm{C}$. At this lower temperature, the cyclisations took up to five hours to go to completion and the addition of dichloromethane was used to prevent the reaction mixture from freezing. Similarly, the two cis-fused perhydrobenzofuran isomers 23 and 24 were obtained from the cis- $(E)$-cyclohexanol 14b but in a more useful ratio of $5: 1$ at $0^{\circ} \mathrm{C}$, improved to ca. 10:1 at $-78^{\circ} \mathrm{C}$. Hence, such cyclisations are indeed viable and, assuming an initial major conformation $\mathbf{8}$ for these substrates, suggest that a late transition state is involved based on the conformation 27 (Fig. 1). The minor isomer 24 could then arise via the less favourable conformation $\mathbf{2 8}$ which would lead to the iodonium ions 29 and 30 and thence to the observed minor product. The much poorer stereoselection obtained from the cyclopentanol 14a is presumably a reflection of the lower energy differences between related conformations in a five-ring system. By contrast, the final series, the cis- $(Z)$-cycloalkanols 16, appeared to have just the right balance between favourable (formation of a cis-fused ring system) and unfavourable (cyclisation onto a ( $Z$ )-alkene) factors. Cyclisations were relatively slow but very clean and gave $>90 \%$ isolated yields of the single diastereoisomers 25 and 26, consistent with conformation 31 (Fig. 1). The more sterically demanding ( $Z$ )-alkene function presumably renders the alternative conformation 32, in which the $\mathrm{C}-\mathrm{OH}$ and alkenyl substituent bonds are aligned in parallel fashion, inaccessible, at least at the present reaction temperature.

We also briefly examined the related bromocyclisation reaction and found that the trans- $(E)$-cyclohexanol 11b could be transformed into the bromoperhydrobenzofuran 33 with the same excellent level of stereoselectivity but required reaction in refluxing carbon tetrachloride when N -bromosuccinimide was the bromonium ion source. The detailed structure of this bromo analogue $\mathbf{3 3}$ was deduced by comparison between its spectral data and those of the corresponding iodo derivative 18 (see below). Finally, partly to extend the synthetic utility of these cyclisations and also to provide additional structural proof of the initial products, we examined methods for the displacement of the iodine by other heteroatoms. Firstly, treatment of the perhydroiodofurans $\mathbf{2 0}$ and $\mathbf{1 8}$ with silver tetrafluoroborate in hot $\mathrm{DMF}^{11}$ gave reasonable isolated yields,

Fig. 1
64 and $77 \%$ respectively, of the formyloxy derivatives 34 and 35. In both cases, the reactions proceeded with complete inversion. This is in direct contrast to the observation made by Bartlett and Ting ${ }^{11}$ that a similar reaction of the annulated iodotetrahydropyran 36 led to the corresponding formyloxy derivative 37 but with retention of configuration. This latter result can be explained by assuming anchiomeric assistance from the ring oxygen and hence the intermediacy of the oxonium species 38 and a double inversion process. Presumably, in the present cases, a similar intermediate 39 is not involved as it is just too strained and hence formation of the observed products 34 and 35 proceeds by a straightforward $\mathrm{S}_{\mathrm{N}} 2$ process. The 2,3trans stereochemistry in the substrate $\mathbf{1 8}$ did not appear to hinder the displacement and formation of the 2,3-cis product 35 was equally facile, at least to a first approximation. This mechanism is also involved in the formation of the azide 40 and the sulfide 41 from perhydroiodofuran $\mathbf{1 8}$; again, the unoptimised yields were acceptable and formation of the more hindered 2,3-cis isomers did not seem to inhibit the displacement significantly. Clearly, these transformations provide an additional set of options for using the initial iodocyclisation products in synthesis.

In all the foregoing cases, once the basic molecular formulae had been established from the usual analytical and spectroscopic data, the detailed structures and stereochemistries were ascertained using extensive NMR experiments. Firstly, it was vital to prove that the products were in fact ring-fused iodotetrahydrofurans rather than the isomeric oxetanes 43 , which could arise from 4-exo cyclisations of the precursors 42. Initially, this was done by assigning a high field methine resonance in the ${ }^{13} \mathrm{C}$ NMR spectrum, positioned around 30 ppm due to a heavy atom effect, ${ }^{12}$ to the CHI group. By a combination of ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ and ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ correlation spectra, this was clearly shown to be positioned between two other methines, one between 75 and 90 ppm and the other at around 30 ppm , assigned to the $2-\mathrm{CHO}$ and $3 \mathrm{a}-\mathrm{CH}$ groups, clearly precluding the oxetane structures 43. The remaining methine resonance in the ${ }^{13} \mathrm{C}$ spectra was then correlated with the other ring junction CHO methine carbon. The remaining features of the spectra, together with coupling constant correlations then confirmed the assigned structures as annulated tetrahydrofurans. Finally, difference nuclear Overhauser enhancement spectra were used to assign the respective stereochemistries, some examples of which are shown in Fig. 2 in which only the positive differences of $>2 \%$ are shown. Other compounds in the series gave much the same results, as detailed in the Experimental section,

thus putting the structural assignments on a firm footing. Similar tactics, especially comparative coupling constant data and difference NOE measurements, were used to deduce the stereochemistries of the derived 3 -substituted analogues 33-35, 40 and 41.

In conclusion, these studies indicate that such overall 5-endo-trig cyclisations represent a generally useful approach to most of the isomers possible for this type of bicyclic system. Although there will clearly be some limitations, the mild conditions suggest that many substituents could be incorporated
into the precursors without a deleterious effect upon the cyclisation, as could additional heteroatoms, especially at various positions in the initial ring.

## Experimental

Infrared spectra were recorded using a Perkin-Elmer 1720 FTIR instrument for thin films between NaCl plates. ${ }^{1} \mathrm{H}$ NMR spectra were recorded using a Bruker WM 250 PFT (250), a JEOL EX270 PFT (270) or a Bruker AM 400 PFT (400) spectrometer. Coupling constants are quoted in hertz. ${ }^{13} \mathrm{C}$ spectra were recorded using the same instruments operating at $62.5,67.5$ and 100 MHz respectively. All spectra were recorded using dilute solutions in deuteriochloroform with tetramethylsilane as an internal standard. Molecular weights and mass spectra were determined using either a VG 7070E or an AEI MS 902 spectrometer, operating in the electron impact mode, unless otherwise stated. All reactions were performed under an atmosphere of dry nitrogen unless otherwise stated and, where appropriate, in oven-dried glassware. All solvents were purified and dried using standard methods. ${ }^{13}$ Petrol refers to the fraction with bp $40-60^{\circ} \mathrm{C}$. Ether refers to diethyl ether. CC indicates column chromatography using SORBSIL $^{R}(40-60 \mu \mathrm{~m})$ silica gel. All solutions from work ups were dried by brief exposure to dried magnesium sulfate followed by filtration.

## trans-2-(Hex-1-ynyl)cyclopentanol 10a

Butyllithium ( 21.0 ml of a 1.6 M solution in hexanes, 33.6 mmol ) was added dropwise during 0.25 h to a stirred solution of hex-1-yne ( $3.86 \mathrm{ml}, 33.6 \mathrm{mmol}$ ) in dry tetrahydrofuran $(50 \mathrm{ml})$, cooled in a solid carbon dioxide-acetone bath. After an additional 20 min at $-78^{\circ} \mathrm{C}$, boron trifluoride-diethyl ether ( $2.75 \mathrm{ml}, 22.4 \mathrm{mmol}$ ) was added dropwise during 5 min and the resulting solution stirred for a further 10 min , before the addition of a solution of cyclopentene oxide $9 \mathbf{a}(1.95 \mathrm{ml}$, 22.4 mmol ) in dry tetrahydrofuran $(5 \mathrm{ml})$ during 2 min . The resulting mixture was stirred for 1.3 h at $-78^{\circ} \mathrm{C}$ then quenched by the addition of saturated aqueous ammonium chloride ( 50 ml ). The resulting mixture was separated and the aqueous layer extracted with ethyl acetate $(3 \times 50 \mathrm{ml})$. The combined organic solutions were dried and evaporated. CC ( $25 \%$ etherpetrol) of the residue gave the hydroxyacetylene 10a ( 2.30 g , $62 \%$ ) as a pale yellow oil, $v_{\max } / \mathrm{cm}^{-1} 3425,2959,2873$ and 2204 ; $\delta_{\mathrm{H}}(250 \mathrm{MHz}) 0.90\left(3 \mathrm{H}, \mathrm{t}, J 6.5, \mathrm{CH}_{3}\right), 1.90(1 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{OH})$, $1.26-2.22(12 \mathrm{H}, \mathrm{m}), 2.54(1 \mathrm{H}, \mathrm{m}, 2-\mathrm{H})$ and $4.11(1 \mathrm{H}, \mathrm{m}, 1-\mathrm{H})$; $\delta_{\mathrm{C}}(67.5 \mathrm{MHz}) 13.6\left(\mathrm{CH}_{3}\right), 18.4,21.8,22.1,31.1,31.3,33.2$ (all $\left.\mathrm{CH}_{2}\right), 38.8(2-\mathrm{CH}), 79.6\left(1^{\prime}\left(2^{\prime}\right)-\mathrm{C}\right), 81.3\left(2^{\prime}\left(1^{\prime}\right)-\mathrm{C}\right)$ and 81.9 (1-CH): $m / z 166$ ( $\mathrm{M}^{+}, 1 \%$ ), 148 (6), 123 (14), 106 (51), 91 (58), 80 (100), 79 (71) and 67 (68) [Found: $\mathrm{M}^{+}, 166.1379 . \mathrm{C}_{11} \mathrm{H}_{18} \mathrm{O}$ requires $M, 166.1358]$.

## trans-2-(Hex-1-ynyl)cyclohexanol 10b

The foregoing method, when applied to cyclohexene oxide $\mathbf{9 b}$ $(4.00 \mathrm{ml}, 39.5 \mathrm{mmol})$ with all other quantities appropriately scaled, gave the hydroxyacetylene $\mathbf{1 0 b}(4.43 \mathrm{~g}, 62 \%)$ as a colourless oil, $v_{\text {max }} / \mathrm{cm}^{-1} 3406,2932,2859$ and $2234 ; \delta_{\mathrm{H}}(270 \mathrm{MHz})$ $0.90\left(3 \mathrm{H}, \mathrm{t}, J 7.1, \mathrm{CH}_{3}\right), 1.08-2.19(15 \mathrm{H}, \mathrm{m}), 2.67(1 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{OH})$ and $3.37(1 \mathrm{H}$, ddd, $J 9.4,9.4$ and $3.9,1-\mathrm{H}) ; \delta_{\mathrm{C}}(100 \mathrm{MHz}) 13.7$ $\left(\mathrm{CH}_{3}\right), 18.5,22.0,24.4,25.0,31.2,31.5,33.0\left(\right.$ all $\left.\mathrm{CH}_{2}\right), 39.2$ $(2-\mathrm{CH}), 74.0(1-\mathrm{CH}), 81.2\left(1^{\prime}\left(2^{\prime}\right)-\mathrm{C}\right)$ and $82.9\left(2^{\prime}\left(1^{\prime}\right)-\mathrm{C}\right)$; $\mathrm{m} / \mathrm{z} 180\left(\mathrm{M}^{+}, 2 \%\right), 162(5), 137$ (27), 120 (44), 105 (35), 95 (54), 91 (72), 84 (59), 79 (81) and 67 (100) [Found: $\mathrm{M}^{+}, 180.1549$. $\mathrm{C}_{12} \mathrm{H}_{20} \mathrm{O}$ requires $\left.M, 180.1514\right]$.

## (1 $\alpha, 2 \beta, E)$-2-(Hex-1-enyl)cyclopentanol 11a

Lithium aluminium hydride-bis(tetrahydrofuran) complex $(7.67 \mathrm{ml}$ of a 1.0 M solution in toluene, 7.67 mmol ) was added dropwise during 2 min to a stirred solution of the hydroxy-
acetylene 10a ( $0.49 \mathrm{~g}, 2.95 \mathrm{mmol}$ ) in dry tetrahydrofuran (20 ml ) and dry toluene ( 20 ml ) at ambient temperature and the resulting mixture stirred at reflux for 48 h . The cooled, stirred mixture was treated cautiously with ethyl acetate ( 20 ml ) and water ( 20 ml ). After 10 min , the two layers were separated and the aqueous layer extracted with ethyl acetate ( $3 \times 30 \mathrm{ml}$ ). The combined organic solutions were dried and evaporated to leave the trans-( $E$ )-cyclopentanol 11a ( $0.432 \mathrm{~g}, 87 \%$ ) as an oil, $v_{\text {max }} / \mathrm{cm}^{-1} 3352,2957,2928,2871$ and $968 ; \delta_{\mathrm{H}}(250 \mathrm{MHz}) 0.89$ ( $3 \mathrm{H}, \mathrm{t}, J 6.9, \mathrm{CH}_{3}$ ), 1.21-2.19 ( $13 \mathrm{H}, \mathrm{m}$ ), 2.21-2.31 ( $1 \mathrm{H}, \mathrm{m}, 2-\mathrm{H}$ ), $3.77-3.85(1 \mathrm{H}, \mathrm{m}, 1-\mathrm{H}), 5.31\left(1 \mathrm{H}, \mathrm{dd}, J 15.3\right.$ and $\left.8.0,1^{\prime}-\mathrm{H}\right)$ and $5.52\left(1 \mathrm{H}\right.$, ddd, $J 15.3,6.7$ and $\left.6.7,2^{\prime}-\mathrm{H}\right)$; $\delta_{\mathrm{C}}(67.5 \mathrm{MHz}) 13.9$ $\left(\mathrm{CH}_{3}\right), 21.0,22.1,29.9,31.6,32.3,33.3\left(\right.$ all $\left.\mathrm{CH}_{2}\right), 51.8(2-\mathrm{CH})$, $78.5(1-\mathrm{CH}), 131.3(=\mathrm{CH})$ and $131.8(=\mathrm{CH}) ; \mathrm{m} / \mathrm{z} 168\left(\mathrm{M}^{+}, 4 \%\right)$, 150 (70), 121 (34), 97 (66), 93 (40), 84 (72), 79 (68), 67 (89) and 55 (100) [Found: $\left.\mathrm{M}^{+}, 168.1500\right]$.

## (1 $10,2 \beta, E)$-2-(Hex-1-enyl)cyclohexanol 11b

By the foregoing method, starting with the acetylenic alcohol 10b ( 0.40 g ), the trans-(E)-cyclohexanol 11b ( $0.324 \mathrm{~g}, 80 \%$ ) was obtained as an oil, $v_{\text {max }} / \mathrm{cm}^{-1} 3330,2928,2856$ and 970 ; $\delta_{\mathrm{H}}(400 \mathrm{MHz}) 0.89\left(3 \mathrm{H}, \mathrm{t}, J 7.1, \mathrm{CH}_{3}\right), 1.14-1.83(14 \mathrm{H}, \mathrm{m})$, $2.01-2.04(1 \mathrm{H}, \mathrm{m}, 2-\mathrm{H}), 2.51(1 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{OH}), 3.18(1 \mathrm{H}$, ddd, $J 9.9,9.9$ and $4.2,1-\mathrm{H}), 5.24\left(1 \mathrm{H}, \mathrm{dd}, J 15.3\right.$ and $\left.8.8,1^{\prime}-\mathrm{H}\right)$ and $5.58\left(1 \mathrm{H}\right.$, ddd, $J 15.3,6.8$ and $\left.6.8,2^{\prime}-\mathrm{H}\right) ; \delta_{\mathrm{C}}(100 \mathrm{MHz})$ $14.0\left(\mathrm{CH}_{3}\right), 22.3,24.9,25.4,31.6,31.7,32.4,33.7\left(\right.$ all $\left.\mathrm{CH}_{2}\right), 50.3$ $(2-\mathrm{CH}), 73.1(1-\mathrm{CH}), 132.0(=\mathrm{CH})$ and $133.7(=\mathrm{CH}) ; ~ m / z 164$ $\left(\mathrm{M}^{+}-\mathrm{H}_{2} \mathrm{O}, 37 \%\right), 121$ (30), 111 (33), 98 (46), 81 (68), 79 (69), 67 (100) and 55 (86) [Found: $\mathrm{M}^{+}-\mathrm{H}_{2} \mathrm{O}, 164.1587 . \mathrm{C}_{12} \mathrm{H}_{20}$ requires $M, 164.1565] .{ }^{14}$

Alternative cyclisation conditions. i) The trans- $(E)$-cyclohexanol 11b ( $0.20 \mathrm{~g}, 1.10 \mathrm{mmol}$ ) was cyclized by the general procedure but using powdered sodium hydroxide $(0.132 \mathrm{~g}$, 3.33 mmol ) as base in place of sodium hydrogen carbonate. Work-up after 1.5 h followed by CC gave the ( $2 \beta, 3 a, 3 a \alpha, 7 a \beta$ )iodofuran 18 ( $0.308 \mathrm{~g}, 91 \%$ ) which displayed spectroscopic and analytical data identical to the foregoing sample.
ii) The trans- $(E)$-cyclohexanol 11b ( $0.20 \mathrm{~g}, 1.10 \mathrm{mmol})$ was cyclized by the general procedure but in the absence of any base. Work-up after 1.5 h followed by CC gave the ( $2 \beta, 3 a, 3 a \alpha, 7 a \beta$ )-iodofuran $18(0.271 \mathrm{~g}, 80 \%)$ which displayed spectroscopic and analytical data identical to the foregoing sample.
iii) To a stirred solution of the trans- $(E)$-cyclohexanol 11b $(0.500 \mathrm{~g}, 2.74 \mathrm{mmol})$ in dry dichloromethane $(20 \mathrm{ml})$ was added $N$-iodosuccinimide $(0.679 \mathrm{~g}, 3.02 \mathrm{mmol})$ and the resulting solution stirred in the dark for 5 h then the solvent evaporated. The residue was triturated with ether $(20 \mathrm{ml})$ and the resulting suspension filtered and the filtrate evaporated. CC gave the ( $2 \beta, 3 a, 3 a \alpha, 7 a \beta$ )-iodofuran $18(0.670 \mathrm{~g}, 79 \%)$ which displayed spectroscopic and analytical data identical to the foregoing sample.
iv) The trans-( $E$ )-cyclohexanol 11b ( $0.20 \mathrm{~g}, 1.10 \mathrm{mmol}$ ) was cyclized by the general procedure but using triethylamine $(0.46 \mathrm{ml}, 3.30 \mathrm{mmol})$ as base in place of sodium hydrogen carbonate. After 30 h at $0^{\circ} \mathrm{C}$, no tetrahydrofuran formation could be detected by either TLC or ${ }^{1} \mathrm{H}$ NMR analysis.
v) The trans- $(E)$-cyclohexanol $11 \mathrm{~b}(0.20 \mathrm{~g}, 1.10 \mathrm{mmol})$ was cyclized by the general procedure but using $N, N$-diisopropylethylamine (Hünig's base; $0.575 \mathrm{ml}, 3.30 \mathrm{mmol}$ ) as base in place of sodium hydrogen carbonate. After 30 h at $0^{\circ} \mathrm{C}$, no tetrahydrofuran formation could be detected by either TLC or ${ }^{1} \mathrm{H}$ NMR analysis.

## (2 $\beta, 3 \beta, 3 a \alpha, 7 a \beta)$ )3-Azido-2-butyloctahydrobenzofuran 40

Sodium azide ( $0.042 \mathrm{~g}, 0.649 \mathrm{mmol}$ ) was added in one portion to a stirred solution of ( $2 \beta, 3 a, 3 a a, 7 a \beta)$-iodofuran $18(0.200 \mathrm{~g}$, $0.649 \mathrm{mmol})$ in dry $N, N$-dimethylformamide ( 15 ml ) and the resulting mixture heated at $110^{\circ} \mathrm{C}$ for 73 h (TLC monitoring). The cooled solution was diluted with ether ( 20 ml ) and water $(20 \mathrm{ml})$ and the resulting layers separated. The aqueous layer was extracted with ether $(2 \times 20 \mathrm{ml})$ and the combined organic solutions washed with water $(4 \times 20 \mathrm{ml})$ then dried and evaporated. CC ( $5 \%$ ether-petrol) of the residue gave the azide $40(0.091 \mathrm{~g}, 63 \%)$ as a colourless oil, $v_{\text {max }} / \mathrm{cm}^{-1} 2936,2861,2101$ and 1146; $\delta_{\mathrm{H}}(400 \mathrm{MHz}) 0.92\left(3 \mathrm{H}, \mathrm{t}, J 7.1, \mathrm{CH}_{3}\right), 1.19-1.25$ $\left(1 \mathrm{H}, \mathrm{m}, 7-\mathrm{H}_{\mathrm{eq}}\right), 1.57-1.64(1 \mathrm{H}, \mathrm{m}, 3 \mathrm{a}-\mathrm{H}), 1.20-1.80(12 \mathrm{H}, \mathrm{m})$, $2.04-2.14\left(1 \mathrm{H}, \mathrm{m}, 7-\mathrm{H}_{\mathrm{ax}}\right), 3.44(1 \mathrm{H}$, ddd, $J 11.9,10.6$ and 4.0 , $7 \mathrm{a}-\mathrm{H}), 3.98(1 \mathrm{H}, \mathrm{dd}, J 4.2$ and $4.0,3-\mathrm{H})$ and $4.07-4.12(1 \mathrm{H}, \mathrm{m}$, $2-\mathrm{H}) ; \delta_{\mathrm{C}}(67.5 \mathrm{MHz}) 14.0\left(\mathrm{CH}_{3}\right), 22.8,23.9,24.9,25.3,28.7$, 30.9, 31.9 (all $\mathrm{CH}_{2}$ ), 50.8 (3a-CH), 66.9 (3-CH), 79.2 and 82.1 (2- and $7 \mathrm{a}-\mathrm{CH}$ ) and $160.4(\mathrm{CO}) ; m / z 167\left(\mathrm{M}^{+}-\mathrm{Bu}, 3 \%\right), 138$ (9), 108 (22), 85 (68), 82 (48), 67 (100), 57 (50) and 54 (38) [Found: C, $64.5 ; \mathrm{H}, 9.4 ; \mathrm{N}, 18.4 . \mathrm{C}_{12} \mathrm{H}_{21} \mathrm{~N}_{3} \mathrm{O}$ requires $\mathrm{C}, 64.5 ; \mathrm{H}$, 9.5; N, 18.8\%].

## (2 $\beta, 3 \beta, 3 \mathrm{a} \alpha, 7 \mathrm{a} \beta$ )-2-Butyl-3-(phenylsulfanyl)octahydrobenzofuran 41

Sodium hydride ( 0.020 g of a $60 \%$ dispersion in oil, 0.487 mmol ) was washed with dry pentane ( $3 \times 3 \mathrm{ml}$ ) and dried under a flow of nitrogen. A solution of thiophenol ( $50 \mu \mathrm{l}, 0.487$ mmol ) in dry $N, N$-dimethylformamide ( 10 ml ) was then added dropwise and the resulting mixture stirred for 10 min at ambient temperature. A solution of the ( $2 \beta, 3 a, 3 a a, 7 a \beta)$-iodofuran 18 $(0.100 \mathrm{~g}, 0.324 \mathrm{mmol})$ in dry $N, N$-dimethylformamide ( 5 ml ) was then added and the resulting mixture heated at $55^{\circ} \mathrm{C}$ for 30 h (TLC monitoring). The cooled mixture was carefully diluted with water ( 10 ml ) and extracted with ether $(2 \times 10 \mathrm{ml})$. The
combined extracts were washed with water $(4 \times 10 \mathrm{ml})$ then dried and evaporated. CC ( $1 \%$ ether-petrol) separated the sulfide $41(0.043 \mathrm{~g}, 45 \%)$ as a colourless oil, $v_{\max } / \mathrm{cm}^{-1} 3057$, 2932, 2858, 1146 and $1075 ; \delta_{\mathrm{H}}(400 \mathrm{MHz}) 0.81(3 \mathrm{H}, \mathrm{t}, J 7.1$, $\left.\mathrm{CH}_{3}\right), 1.05-1.19\left(1 \mathrm{H}, \mathrm{m}, 7-\mathrm{H}_{\mathrm{eq}}\right), 1.06-1.74(11 \mathrm{H}, \mathrm{m}), 1.44(1 \mathrm{H}$, dddd, $J 12.1,12.1,12.1$ and $\left.3.4,4-\mathrm{H}_{\mathrm{ax}}\right), 1.80-1.87(1 \mathrm{H}, \mathrm{m}$, $3 \mathrm{a}-\mathrm{H}), 2.07-2.10\left(1 \mathrm{H}, \mathrm{m}, 7-\mathrm{H}_{\mathrm{ax}}\right), 3.49(1 \mathrm{H}$, ddd, $J 10.6,10.6$ and $5.9,7 \mathrm{a}-\mathrm{H}), 3.78(1 \mathrm{H}, \mathrm{dd}, J 5.0$ and $5.0,3-\mathrm{H}), 4.19-4.24(1 \mathrm{H}, \mathrm{m}$, $2-\mathrm{H}), 7.05-7.25(3 \mathrm{H}, \mathrm{m})$ and $7.31(2 \mathrm{H}, \mathrm{d}, J 7.3)$; $\delta_{\mathrm{C}}(100 \mathrm{MHz})$ $14.0\left(\mathrm{CH}_{3}\right), 22.8,23.9,25.3(\mathrm{all} \mathrm{CH}), 26.6\left(4-\mathrm{CH}_{2}\right), 28.9\left(\mathrm{CH}_{2}\right)$, $32.1\left(7-\mathrm{CH}_{2}\right), 32.7\left(\mathrm{CH}_{2}\right), 51.3(3 \mathrm{a}-\mathrm{CH}), 55.2(3-\mathrm{CH}), 79.8(7 \mathrm{a}-$ $\mathrm{CH}), 82.2(2-\mathrm{CH}), 126.0\left(4^{\prime}-\mathrm{CH}\right), 128.8\left(2 \times 3^{\prime}-\mathrm{CH}\right), 130.0$ $\left(2 \times 2^{\prime}-\mathrm{CH}\right)$ and $137.2\left(1^{\prime}-\mathrm{C}\right)$; $m / z[\mathrm{FAB}] 291\left(\mathrm{M}^{+}+\mathrm{H}, 64 \%\right)$, 290 (86), 289 (54), 204 (85), 181 (66), 123 (45), 95 (87), 81 (76), 68 (67) and 56 (100) [Found: $\mathrm{M}^{+}, 290.1703 . \mathrm{C}_{18} \mathrm{H}_{26} \mathrm{OS}$ requires M, 290.1704].
