5-Formyl- and 5-acetyl-4-(alkenylamino)pyrimidines 5 have been prepared as precursors to novel pyrimido[1,4]diazepine $N$-oxides 3. In addition to cyclisation to the targeted dipoles the substrates $\mathbf{5}$ have also been observed to form imidazopyrimidines $\mathbf{1 2}$ and $\mathbf{3 9}$ via an intramolecular Michael addition; additionally $\mathbf{5 b}$ has been observed to form the pyrimidoazepinone $\mathbf{4 2}$. Aldonitrone 3a cycloadded readily to olefinic dipolarophiles; ketodipole $\mathbf{3 b}$ did not share this reactivity. Both dipoles reacted with acetylenic dipolarophiles but the ensuing cycloadducts $\mathbf{3 7}$ were unstable; facile ring contraction of their isoxazolopyrimidodiazepine skeletons to the pteridine nucleus is noted. The structure of $\mathbf{3 7} \mathbf{c}$ has been determined by X-ray crystallography.

## Introduction

Pyrimidines and their ring fused derivatives have a broad spectrum of biological activity; best known as the heterocyclic core of the nucleic acid bases, these ring systems are often incorporated into drugs designed for cancer and anti-viral treatment. ${ }^{1}$ We have been investigating the preparation and cycloaddition potential of 1,4-benzodiazepinone $N$-oxides ${ }^{2} \mathbf{1}$

and more recently have turned our attention to a hitherto unknown series of pyrimidine compounds, the isoxazolopyrimidodiazepines 2. 8,9-Dihydro-7 H -pyrimido $[4,5-e][1,4]-$ diazepine $N^{6}$-oxides, 3 , were the target nitrones and their synthesis from (alkenylamino)pyrimidines 5 was envisaged (Scheme 1). Similar substrates have been widely investigated by Noguchi's group in their comprehensive study of the preparation of fused azepine rings by intramolecular thermal ene reactions (carbonyl, imine or hydrazone). ${ }^{3}$ In a recent communication we reported that the preparation of compounds like 5 from a condensation reaction of a secondary amine with a
chloropyrimidine proceeded in high yield only when the amino component did not carry an $\alpha$-substituent. ${ }^{4}$

## Results and discussion

The general approach to the preparation of $\gamma$-aminocrotonates related to 7 involves nucleophilic displacement of an allylic halide or nosylate ( $p$-nitrobenzenesulfonate) from the appropriate crotonate. ${ }^{5}$ The amine 7 was prepared from reaction of methyl 4-bromobut-2-enoate with benzylamine. The identity of the reaction product is sensitive to the experimental conditions. With an equimolar ratio of reactants the $N, N$-bisalkylated compound $\mathbf{8}$ is the major product ( $69 \%$ ); moderate yields of the corresponding diesters were obtained by Rahman and coworkers ${ }^{6}$ on reaction of primary alkyl amines with the same bromobutenoate. The optimal yield of $7(65 \%)$ was obtained following reaction with three equivalents of benzylamine $\left(\mathrm{Et}_{2} \mathrm{O}\right.$, $0^{\circ} \mathrm{C}$ ). With a large excess of benzylamine, 10 equivalents, the 4 -aminopyrrolidinone 9 resulted ( $100 \%$ ). The lactam likely arises from 7 in two steps, viz. an initial Michael type addition of a second molecule of $\mathrm{BnNH}_{2}$, giving $\mathbf{1 0}$, followed by a 5 -exotrig cyclisation. Alternatively $\mathbf{1 0}$ may arise from $\mathbf{7 v i a}$ an initial shift of the amino group from the external to the internal position by way of an aziridine intermediate, $\mathbf{1 1}$ and ring opening by amine attack at the less substituted ring carbon ${ }^{7}$ (Scheme 2).
The condensation between the allylic amine 7 and the

chloropyrimidine $\mathbf{6 a}$ furnished $\mathbf{5 a}$ in high yield (78\%) following stirring in $\mathrm{CHCl}_{3}$ at rt in the presence of triethylamine. We anticipated a straightforward carbonyl to oxime functionalisation on reaction of 5 a with $\mathrm{NH}_{2} \mathrm{OH}$, however a number of products resulted from this reaction. The starting aldehyde 5a and the proposed oxime $\mathbf{4 a}$ both have a high density of functionality and imidazopyrimidines $\mathbf{1 2 a}, \mathbf{b}$ can arise from these

c $\mathrm{R}=\mathrm{Me}, \mathrm{X}=\mathrm{O}$
substrates by cyclisation of the nucleophilic pyrimidine nitrogen atom onto the pendant electrophilic alkene. ${ }^{4}$ The oxime 4 has two further channels for reactivity, viz. tautomerisation to the corresponding NH -dipole $\mathbf{1 3}$ with subsequent cycloaddition to $\mathbf{1 4}$ [intramolecular oxime olefin cycloaddition, IOOC, Fig. 1], ${ }^{8}$ or 7-exo-trig cyclisation to the targeted pyrimidodiazepine $N$-oxide 3a [azaprotio cyclotransfer reaction, APT, ${ }^{9}$ Fig. 2]. The conditions best disposed to nitrone formation employed MeOH at $0^{\circ} \mathrm{C}$, whence 3a was isolated in $65 \%$ yield accompanied by $14 \%$ of the tricyclic isoxazolopyridopyrimidine 14 [IOOC product], $5 \%$ of the imidazopyrimidine 12a and $5 \%$ of the corresponding oxime 12b.

Fig. 2
The isoxazolopyridopyrimidine $\mathbf{1 4}$ is furnished diastereospecifically and has cis ring junction stereochemistry as indicated by both coupling constant [ $J_{9 \mathrm{~b}, 3 \mathrm{a}} 6.01 \mathrm{~Hz}$ ], and nuclear Overhauser enhancement difference spectroscopy results (NOEDS), summarised in Fig. 1]. Intramolecular cycloaddition of related azomethine ylides, nitrile oxides and nitrile imines giving 5,6,6-ring systems, pyrrolo- 15, isoxazolo- 16 and

pyrazolo-pyridopyrimidines $\mathbf{1 7}$ have been reported. ${ }^{10}$ In a closer parallel Noguchi has demonstrated, and afforded a mechanistic proposal for, an IOOC reaction of a pyrido[1,2-a]pyrimidine system, ${ }^{8 e}$ e.g. the oxime 18 upon heating in EtOH afforded the

tetracycle 19a in $93 \%$ yield; when the reaction solvent was changed to $\mathrm{C}_{6} \mathrm{H}_{6}$ diastereomeric adducts $\mathbf{1 9 a}, \mathbf{b}$ ( $76 \%$ and $14 \%$ yield respectively) were obtained together with the tricyclic $N$-oxide $20(8 \%)$. The product distribution with Noguchi's substrate differs significantly from ours; the low yield of the dipole and the absence of any imidazo fused adducts is a consequence of the electronically neutral pendant double bond in 18. The corresponding centre in $\mathbf{4 a}$ carries a methoxycarbonyl substituent which facilitates nucleophilic attack by the oxime or pyrimidine nitrogen atoms furnishing dipole 3a and imidazopyrimidines $\mathbf{1 2 a} / \mathbf{b}$ respectively. In keeping with the requirement for a high degree of electrophilicity at the unsaturated centre it is perhaps not surprising that the terminally unsubstituted alkynyl substrate 21 failed to partake in any ring forming reactions. After several hours heating alone or in the presence of $\mathrm{AgBF}_{4} 21$ was returned unchanged. The nitrone forming power of the intramolecular oxime-alkyne cyclisation reaction has been demonstrated thermally for 6 -membered dipoles ${ }^{11}$ and $\operatorname{Ag}(\mathrm{I})$ catalysed oxime-allene cyclisation leading to $5-$ and 6-membered nitrones has been reported. ${ }^{12}$ The cyclisation of 21

21
has both electronic and geometrical disadvantages when compared with substrates like 4 and thus has a prohibitively high activation energy.

Cycloaddition of nitrone 3a to $N$-methylmaleimide (THF, rt, $24 \mathrm{~h})$ proceeded with high diastereofacial selectivity; the major adduct $\mathbf{2 2}$ was isolated in $73 \%$ yield and a second isomer too

Fig. 3 NOEDS results for compound 22
small in quantity to be isolated was seen in the ${ }^{1} \mathrm{H}$ NMR spectrum of the crude reaction mixture. The relative stereochemistry of 22, the first example of this ring system, is tentatively assigned as shown following NOEDS experiments; the pertinent results are summarised in Fig. 3. That the 12a- and 12b-protons are cis is evident from their mutual enhancement upon irradiation of each other $(\sim 6 \%)$. On its own the small enhancement ( $\sim 1 \%$ ) on $7-\mathrm{H}$ following irradiation of $12 \mathrm{~b}-\mathrm{H}$ is insufficient to confidently assign these protons as being cisorientated; however this proposal is indirectly supported by the following enhancements: $12 \mathrm{~b}-\mathrm{H}$ to $6-\mathrm{H}(\sim 5 \%)$ and $6-\mathrm{H}$ to $7-\mathrm{H}$ $(\sim 2 \%)$. The tetracyclic skeleton of $\mathbf{2 2}$ thus arises from a transition state involving an endo-addition of the dipolarophile to the face of the dipole carrying the $\mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{Me}$ substituent.

Cycloaddition to monosubstituted olefinic dipolarophiles progressed in much poorer chemical yield and showed varying degrees of selectivity. On reaction of 3a with methyl vinyl ketone four adducts, 23-26, were isolated in 23, 12, 18 and $41 \%$ yields respectively (based on $53 \%$ conversion of nitrone). The first three, 23-25, are stereoisomeric adducts with the acyl sub-

$\mathrm{C}_{6} \mathrm{D}_{6}$. Irradiation of the signal representing 7-H $\left(\mathrm{CDCl}_{3}\right)$ caused a $\sim 1 \%$ enhancement on the signal for 11a-H (reciprocated on back irradiation of 11a-H) (Fig. 4). Since the tricycle has conformational freedom it is difficult to correlate the small cross ring enhancement with a cis-relationship between these protons; however this value is very similar to that observed for the maleimide adduct $\mathbf{2 2}$ where the corresponding protons were indirectly shown to be in close proximity. The minor adduct 32 ( $34 \%$ ) has limited stability in $\mathrm{CDCl}_{3}$, consequently spectra were recorded in $\mathrm{C}_{6} \mathrm{D}_{6}$; unfortunately in this solvent $10-\mathrm{H}$ and $7-\mathrm{H}$ were coincident, prohibiting any chance to ascertain the cross ring stereochemistry. Irradiation of the signal representing 11-H caused a $\sim 16 \%$ enhancement on the signal for 11a-H; this adduct therefore results from an endo addition of phenyl vinyl sulfone to one face of the dipole.
Dimethyl fumarate was expected to be a good candidate for cycloaddition with $3 \mathrm{a},{ }^{14}$ accordingly these components were

stirred in THF at rt. Reaction progress was monitored by TLC and appeared to progress toward cycloadduct formation. However, following chromatographic separation $\left(\mathrm{SiO}_{2}, \mathrm{Et}_{2} \mathrm{O}\right.$, petroleum ether), ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right)$ analysis of the fractions considered as pure cycloaddition product indicated the presence of three compounds: cycloadduct $\mathbf{3 3}$ as well as starting nitrone and dimethyl fumarate. Evidently the adduct is quite unstable and retrocycloaddition begins almost immediately in $\mathrm{CDCl}_{3}$ and is complete on standing at rt for 3 d . Varying degrees of instability are noted in other deuterated solvents $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right.$, THF- $\mathrm{d}_{8}, \mathrm{CD}_{3} \mathrm{CN}$, acetone- $\mathrm{d}_{6}$, toluene- $\mathrm{d}_{8}$ ). Repulsive steric interactions are likely responsible for the instability of $\mathbf{3 3}$ which has a greater degree of substitution than the adducts previously discussed. High cycloreversion rates for adducts of cyclic nitrones with dimethyl fumarate/maleate have been noted previously, e.g. in studues by Gandolfi and co-workers with dihydroisoquinoline $N$-oxide 34 equilibrium was established between the diastereomeric cycloadducts $\mathbf{3 5}$ and $\mathbf{3 6} ;{ }^{15}$ for our more highly substituted dipole equilibrium is between cycloadduct and reactants. The reaction of 3a with fumarate was repeated, firstly on an analytical scale at rt in acetone (slowest retrocycloaddition rate) with an excess of one reactant (fumarate, 10 equivalents) and progress was followed by HPLC. Enhancement of intensity of the signal occurred due to product stabilised after 27 h stirring. An independent HPLC measurement showed the position of the equilibrium to be sensitive to temperature, with lower temperatures ( $4^{\circ} \mathrm{C}$ ) favouring cycloadduct. On scale-up a fresh sample of $\mathbf{3 3}$ was isolated and ${ }^{1} \mathrm{H}$

Fig. 6

NMR spectra were recorded in toluene- $\mathrm{d}_{8}$ at $-60^{\circ} \mathrm{C}$. In addition to resonance signals characteristic of the tricycle the spectrum showed a small number of signals (of low intensity) not immediately attributable to cycloadduct or its precursors. It is plausible that these "additional" signals represent a minor conformer ("hidden partner") of the tricyclic framework. ${ }^{13}$

Reaction of 3a with dimethyl acetylenedicarboxylate in THF at $0^{\circ} \mathrm{C}(24 \mathrm{~h})$ led to a number of new compounds. Attempts to separate the crude material by flash chromatography further increased the complexity of the mixture and only a small amount ( $7 \%$ ) of cycloadduct was isolated. ${ }^{1} \mathrm{H}$ NMR analysis of this material shows resonance signals characteristic of the protons of 37a (Fig. 5). A second product, isolated in $10 \%$ yield, was later identified as the pteridine 43. In common with most 4 -isoxazolines ${ }^{16} \mathbf{3 7 a}$ is rather unstable and it readily decomposed. Examination of the components of thermal decomposition showed 37a to be a precursor of 43.

The presence of a methyl substituent at the $C$-position of the dipole $\mathbf{3}$ is likely to exert modest steric demands and could be expected to influence the reactivity, regio- and stereoselectivity of any cycloaddition reactions. Further, the presence of such a substituent will influence the conformational properties of the ensuing cycloadducts. Gilman and co-workers have reported that the introduction of a $\mathrm{Bu}^{t}$ group at the $\mathrm{N}-1$ position of diazepam effectively inhibits conformational racemisation and synthesis of each enantiomer becomes possible ${ }^{17}$ (Fig. 6).

The ketodipole $\mathbf{3 b}$ has been prepared by a reaction sequence parallel to that described for the aldonitrone 3a. The acyl-

6b

Scheme 3
pyrimidine $\mathbf{6 b}$ resulted from PCC oxidation of the alcohol 38 ( $87 \%$ ), itself prepared from commercially available 6 -chloro-2,4-dimethoxypyrimidine. Condensation of $\mathbf{6 b}$ with $\mathbf{7}$ gave $\mathbf{5 b}$ in $82 \%$ yield. Treatment of $\mathbf{5 b}$ with $\mathrm{NH}_{2} \mathrm{OH}$ was expected to furnish 3b via an oximation-cyclisation sequence. However imidazopyrimidine formation competed and 12c and 39 were isolated together with nitrone. A key feature in distinguishing between the two imidazopyrimidines is the ${ }^{13} \mathrm{C}$ resonance position of the C-5 carbon atom; in 12c this is an "oxo" carbon and resonates at $\sim 155 \mathrm{ppm}$ whilst in 39 this position is an "hydroxyimino" carbon and it resonates at $\sim 147 \mathrm{ppm}$. Further the mass spectrum of $\mathbf{3 9}$ has molecular ion at 387. In the best experiment both base and hydroxylamine hydrochloride were used in excess; pyridine was employed as the reaction solvent and a fivefold excess of $\mathrm{NH}_{2} \mathrm{OH} \cdot \mathrm{HCl}$ was used (rt, 48 h ). These conditions furnished nitrone $\mathbf{3 b}$ ( $49 \%$ ) as well as imidazopyrimidines 12c $(25 \%)$ and $39(24 \%)$. Reaction in MeOH with pyridine as base ( $\mathrm{rt}, 24 \mathrm{~h}$ ) gave the dipole 3b ( $12 \%$ ) and the 5 -oxoimidazopyrimidine 12c ( $65 \%$ ) as the only products whilst a $\mathrm{MeOH}, \mathrm{NaHCO}_{3}$ combination (rt, 72 h ) gave nitrone 3b (41\%) and the 5 -(hydroxyimino)imidazopyrimidine 39 ( $52 \%$ ). In MeOH pyridine functions as a homogeneous base whilst $\mathrm{NaHCO}_{3}$ will remain a solid; this difference and their different $\mathrm{p} K_{\mathrm{a}}$ values [pyridine 5.25 and $\mathrm{NaHCO}_{3} 6.35$ ] may influence the pH of the reaction medium and the availability of free $\mathrm{NH}_{2} \mathrm{OH}$ for reaction and so account for the different product distribution. Thus 12c, the dominant product from reaction using an (approximately) equimolar quantity of pyridine does not require $\mathrm{NH}_{2} \mathrm{OH}$ for its formation whilst the generation of both 3b and 39, the products of reaction employing $\mathrm{NaHCO}_{3}$ as base, does involve $\mathrm{NH}_{2} \mathrm{OH}$. A plausible origin of $\mathbf{1 2 \mathrm { c }}$ and $\mathbf{3 9}$ is summarised in Scheme 3. The different products are likely a consequence of the nature of the attacking species- $\mathrm{H}_{2} \mathrm{O}$, MeOH or $\mathrm{NH}_{2} \mathrm{OH}$ - on the intermediate zwitterion 40 with 41a being the precursor to $\mathbf{1 2 c}$ and 41b leading to $\mathbf{3 9}$. Finally when 5b was heated alone in MeOH the pyrimidoazepinone 42 ( $74 \%$ ) and the 5 -oxoimidazopyrimidine 12c ( $25 \%$ ) were formed. Presumably $\mathbf{4 2}$ arises via Michael attack of the enolate of $\mathbf{5 b}$ onto

the internal double bond with the tertiary amine functionality behaving as base (either inter- or intramolecularly); its formation indicates yet another available reaction path for this densely functionalised substrate. Pyrimido[4,5-b]azepin-5ones have previously been considered as potentially interest-
ing synthetic intermediates in the preparation of folic acid derivatives. ${ }^{18}$
The keto dipole 3b failed to cycloadd to any of $N$-methylmaleimide, methyl vinyl ketone, dimethyl fumarate/maleate or phenyl vinyl sulfone, returning unchanged starting materials after stirring at elevated temperatures. However it did react with acetylenic substrates, methyl propiolate and dimethyl acetylenedicarboxylate. The reaction of $\mathbf{3 b}$ with dimethyl acetylenedicarboxylate after 72 h stirring in THF yielded only a small sample of one cycloadduct ( $6 \%$ ); ${ }^{1} \mathrm{H}$ NMR data supports its assignment as $\mathbf{3 7 b}$ and due to the instability of the cycloadduct no further analytical data could be acquired. The major product was characterised as the pteridine $\mathbf{4 3}(47 \%)$. If $\mathbf{3 7 b}$ is heated alone in boiling MeOH quantitative conversion to $\mathbf{4 3}$ occurs after 2 h .

44
On stirring 3b at rt ( 24 h ) with excess methyl propiolate (as solvent and reactant) three new products, the " 4 -substituted" isoxazoline, $\mathbf{3 7} \mathbf{c}(42 \%)$, the $\mathrm{NH}-43(17 \%)$ and the N -substituted $44(23 \%)$ pteridines, were formed. Full characterisation of the primary cycloadduct, 37c, by NMR spectroscopy proved impossible as decomposition took place in $\mathrm{CDCl}_{3}$ during the time span required for acquisition of ${ }^{13} \mathrm{C}$ data. However, the adduct was stable in the solid phase and crystals suitable for X-ray analysis were obtained from petroleum ether- $\mathrm{Et}_{2} \mathrm{O}$. The ORTEX drawing of 37c (Fig. 7), shows the tricyclic skeleton to adopt the folded rather than the extended conformation. ${ }^{13 a}$ The hydrogen on $C(9)$ and the methyl group on $C(10)$ are on the same side of the fused ring system. However the molecule is not flat at the fusion point with the $\mathrm{C}(20)-\mathrm{C}(10)-\mathrm{N}(2)-\mathrm{C}(9)$ dihedral angle being $91^{\circ}$. The hydrogen atom on $C(9)$ is $4.158 \AA$ from the mean of the hydrogens on the methyl group. This interproton distance is close to the limit for detection of nuclear Overhauser effects. That the tricycle 37c is the precursor of the NH -pteridine has been illustrated; thus simply heating 37c alone in boiling MeOH furnishes 43 in $95 \%$ yield. That the $N$-substituted pteridine 44 arises from the unsubstituted parent by a pseudo Michael addition reaction to a molecule of methyl propiolate was also verified by an independent experiment. The pteridine nucleus is the product of a thermal ring contraction of the isoxazolopyrimidodiazepine skeleton and the rearrangement of 37c likely follows the mechanism suggested by Freeman

Fig. 7 ORTEX Drawing of 37c. Crystallographic numbering system shown.
and co-workers for isoxazolobenzodiazepines, involving a 1,2-carbon-to-nitrogen shift followed by cleavage of the $\mathrm{N}-\mathrm{O}$ bond of the isoxazoline ring ${ }^{19}$ as outlined in Scheme 4. An

Scheme 4
analogous rearrangement explains the formation of $\mathbf{4 3}$ from 37a,b.

Pteridines, being widely distributed in nature, are of general interest due to their potential biological activity. They are most commonly synthesised starting from a condensation reaction of a 5,6-diaminopyrimidine (Gabriel-Isay reaction or modification of) or much less commonly from a pyrazine nucleus; ${ }^{20}$ their preparation by transformation of other heterocyclic rings is much less common. This is the first example of a pteridine synthesis by ring contraction of an isoxazolopyrimidodiazepine.

## Conclusion

Pyrimido[1,4]diazepine $N$-oxides have been prepared for the first time and the cycloadditive ability of $\mathbf{3}$ has been shown to be dependent on the degree of substitution at the C -atom of the dipole. The aldonitrone 3a reacts with both olefinic and acetylenic substrates whilst the $C$-substituted dipole $\mathbf{3 b}$ is inactive to olefinic dipolarophiles. With monosubstituted olefins 3a displays a preference for formation of 4 -substituted isoxazolidine rings. The diastereoselectivity of the cycloaddition is lowest with methyl vinyl ketone and highest with N -methylmaleimide. The dimethyl fumarate cycloaddition product had a short lifetime at rt and underwent retrocycloaddition to exist in equilibrium with the starting nitrone 3a and dipolarophile. Both
dipoles react with acetylenic substrates but the primary adducts have a low degree of stability and readily rearrange to the pteridine nucleus. This ring contraction may be a useful route to synthesis of unusually substituted pteridines.

## Experimental

Melting points were determined on an Electrothermal melting point apparatus and are uncorrected. Elemental analyses were performed on a Perkin-Elmer model 240 CHN analyser. NMR spectra were recorded using a JEOL JNM-LA400FT NMR instrument operating at 400 MHz for ${ }^{1} \mathrm{H}$ and 100 MHz for ${ }^{13} \mathrm{C}$ nuclei with tetramethylsilane as internal reference; $J$ values are given in Hz. Mass spectroscopy was performed on a Profile Kratos Analytical Instrument. Flash chromatography was carried out on silica gel (200-400 mesh; Kieselgel 60, E. Merck) with air pump pressure. Analytical TLC plates were purchased from Merck. Samples were located by UV illumination using a portable Spectroline Hanovia lamp ( $\lambda=254 \mathrm{~nm}$ ) or by the use of iodine staining. All solvents used were purified by standard procedures and petroleum ether refers to fractions of light petroleum boiling between $40-60^{\circ} \mathrm{C}$.

A solution of methyl 4-bromocrotonate ( $1.00 \mathrm{~g}, 5.6 \mathrm{mmol}$ ) in $\mathrm{Et}_{2} \mathrm{O}\left(3 \mathrm{~cm}^{3}\right)$ was added slowly to a solution of benzylamine ( 10 equivalents, $6.0 \mathrm{~g}, 56 \mathrm{mmol}$ ) in $\mathrm{Et}_{2} \mathrm{O}\left(20 \mathrm{~cm}^{3}\right)$ at $0{ }^{\circ} \mathrm{C}$. The resulting mixture was stirred at $0{ }^{\circ} \mathrm{C}$ for 24 h , then concentrated under reduced pressure. The residue was dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $50 \mathrm{~cm}^{3}$ ), washed with brine ( $3 \times 50 \mathrm{~cm}^{3}$ ), dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and reconcentrated under reduced pressure. Purification by flash chromatography ( $\mathrm{Et}_{2} \mathrm{O}$-petroleum ether $1: 1$ ) afforded three pure products, which are listed in order of elution. X-Ray crystal determination of 37c.§ The structure was solved by direct methods, SHELXS-97, ${ }^{23}$ and refined by full matrix least squares using SHELXL-97. ${ }^{24}$ SHELX operations were rendered paperless using ORTEX which was also used to obtain the drawings. ${ }^{25}$ Data were corrected for Lorentz and polarisation effects but not for absorption. Hydrogen atoms were included in calculated positions with thermal parameters $30 \%$ larger than the atom to which they were attached. The nonhydrogen atoms were refined anisotropically. All calculations were performed on a Pentium PC. Crystal data for $\mathbf{3 7} \mathbf{c}$ are given in Table 2.
