Testudinariols $\mathrm{A}(\mathbf{1})$ and $\mathrm{B}\left(\mathbf{1}^{\prime}\right)$ are ichthyotoxic and structurally unusual triterpene alcohols isolated from the skin and the mucus of the marine mollusc Pleurobrancus testudinarius. The first synthesis of $(+)-\mathbf{1}$ and $(+)-\mathbf{1}^{\prime}$ was achieved by starting from ( $R$ )-glycidol.

## Introduction

In 1997, Spinella et al. isolated testudinariol A (1) and its $\mathrm{C}-10^{\prime}$ epimer, testudinariol $\mathrm{B}\left(\mathbf{1}^{\prime}\right)$ (Fig. 1) as metabolites of the marine mollusc Pleurobrancus testudinarius. ${ }^{2}$ These compounds are structurally unique triterpene alcohols and thought to be defensive allomones of $P$. testudinarius, because 1 was ichthyotoxic against Gambusia affinis. The partially cyclized squalene skeleton present in $\mathbf{1}$ and $\mathbf{1}^{\prime}$ is biosynthetically unusual, since the general biosynthetic pathway for polycyclic triterpenoid via squalene 2,3 -oxide does not provide such a carbon skeleton. Only two similar skeletons have been reported, in the cases of limatulones [ $\mathbf{2}$ and $\mathbf{2}^{\prime}$, defensive metabolites of the limpet Achmeia (Collisella) limatula ${ }^{3}$ and naurols ( $\mathbf{3}$ and $\mathbf{3}^{\prime}$, metabolites of the marine sponges with cytotoxicity to murine leukemia cells P388). ${ }^{4}$ All of these natural products are $C_{2}$-symmetric triterpene alcohols or their diastereomers. We became interested in the unique structures of these marine triterpenoids and have studied their synthesis. Up to the present, synthesis of $\mathbf{2}$, $\mathbf{2}^{\prime 5}$ and $\mathbf{3}^{1}$ has been accomplished and reported by us. Very recently, we achieved the first synthesis of $(+)-1$ and reported it as a preliminary communication. ${ }^{6}$ Herein the synthesis of testudinariols $\mathrm{A}(\mathbf{1})$ and $\mathrm{B}\left(\mathbf{1}^{\prime}\right)$ will be described in detail.

## Results and discussion

## Synthetic plan

Scheme 1 shows our synthetic plan for testudinariol A (1). Because a structural feature of target compound $\mathbf{1}$ is its $C_{2}$ symmetry, $\mathbf{1}$ can be obtained by dimerization or its equivalent operation of $\mathbf{A}$. The intermediate $\mathbf{A}$ may be prepared from $\mathbf{B}$ by $(Z)$-selective installation of the two-carbon appendage. For the stereoselective construction of the cyclopentane portion of $\mathbf{B}$, an intramolecular ene reaction is appropriate employing $\mathbf{C}$ as the substrate. The intramolecular oxy-Michael-type cyclization of $\mathbf{D}$ has been adopted to prepare the tetrahydropyran ring of C. The intermediate $\mathbf{D}$ can be synthesized from $\mathbf{F}[(R)$-glycidol] via the known diol $\mathbf{E} .{ }^{7}$ This synthetic plan is also applicable to the synthesis of testudinariol B(1').

## Synthesis of testudinariol A

The starting $(R)$-glycidol $(\mathbf{4},=\mathbf{F})$ was converted to the known diol 5 (=E) (Scheme 2). ${ }^{7}$ Selective TBDMS protection of the primary hydroxy group of $\mathbf{5}$ was followed by treatment with 4-methoxybenzyl trichloroacetimidate ${ }^{8}$ to give $\mathbf{6 b}$ ( $77 \%$ yield, 2 steps). The enantiomeric purity of $\mathbf{6 b}$ was determined by HPLC

This ether $\mathbf{6 b}$ was subjected to $\mathrm{OsO}_{4}$ mediated dihydroxylation and subsequently treated with $\mathrm{NaIO}_{4}$ to furnish $\mathbf{8}(91 \%, 2$ steps). The aldehyde $\mathbf{8}$ was then employed for the Horner-Wadsworth-Emmons (HWE) reaction with ethyl 2-diethoxyphosphoryl-6-methylhept-5-enoate ${ }^{9}$ (9) under several different conditions, and the use of $\mathrm{Bu}^{t} \mathrm{OK}$ in toluene as the base at $-20^{\circ} \mathrm{C}$ provided the best result, furnishing $\mathbf{1 0 a}$

in $93 \%$ yield ( $E: Z=5: 1$ ). Although these conditions resulted in the best $(E)$-selectivity, it turned out that $(E)$-geometry was not important for the diastereoselectivity in the later Michaeltype cyclization. After removal of the TBDMS protective group $(99 \%)$, the resulting $\mathbf{1 0 b}(=\mathbf{D})$ was exposed to one of the key steps, intramolecular Michael-type cyclization.
Table 1 summarizes the results of our studies on diastereoselective cyclization. Our first attempt to obtain the desired diastereomer 11a as the predominant product under kinetic control was unfortunately problematic. Although a wide range of bases, $\mathrm{NaH}, \mathrm{LiH}, \mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{Cs}_{2} \mathrm{CO}_{3}$, TBAF, etc., and Lewis acids, $\mathrm{ZnCl}_{2}, \mathrm{Sc}(\mathrm{OTf})_{3}, \mathrm{TiCl}_{4}$, etc., were examined under various conditions, appropriate conditions to furnish 11a diastereoselectively could not be established. We then tried to obtain a mixture of all of the possible diastereomers under thermodynamic control. Thus, 10b was treated with $\mathrm{Bu}^{t} \mathrm{OK}$ ( 0.1 eq.) in THF at -10 to $4^{\circ} \mathrm{C}$ to give, in $93 \%$ yield, a mixture of 11a-d (11a:11b $: 11 \mathbf{c}: 11 \mathrm{~d}=5: 5: 2: 2$, as determined by ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analysis). Under these conditions, the geometry of the conjugated double bond did not play any role in determining diastereoselectivity, and the ratio of the products reflected the thermodynamic equilibrium.
Stereochemical assignment of 11a-d was achieved as follows. At first, trans- or cis-2,5-substitution on the tetrahydropyran ring could easily be deduced based on the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ analysis of 11a-d. However, the orientation of the homoprenyl group was difficult to deduce. Therefore, 11a and 11b, whose stereostructures were uncertain at the time, were reduced with DIBAL-H to afford $\mathbf{1 4 a}$ and $\mathbf{1 4 b}$, respectively. The observed ${ }^{1} \mathrm{H}-\mathrm{NMR}$ data including NOE correlation depicted in Fig. 2 suggested that the stereostructures of 14a and 14b (hence 11a and 11b) were as illustrated therein. In the same manner, the stereostructures of 11c and 11d were also elucidated. Although the desired 11a was not predominant, chromatographic separation of diastereomers was possible, and the undesired three isomers (11b-d) could be recycled to the initial mixture by treatment with $\mathrm{Bu}^{t} \mathrm{OK}$ at $4^{\circ} \mathrm{C}$. By repeating this process three times, 11a was obtained in $68 \%$ overall yield.
The next challenge was the stereoselective construction of the cyclopentane fragment. As mentioned in the synthetic plan, an ene reaction was thought to be appropriate, and the aldehyde

12 (= C), which was prepared by DIBAL-H reduction of 11a ( $98 \%$ ), was submitted to it (Scheme 3). As shown in Table 2, when aldehyde 12 was treated with $\mathrm{Me}_{2} \mathrm{AlCl}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}{ }^{10}$ at $0{ }^{\circ} \mathrm{C}$, the desired 13a $(=\mathbf{B})$ was generated as the major isomer in a moderate selectivity ( $\mathbf{1 3 a}: \mathbf{1 3 b}: \mathbf{1 3} \mathbf{c}=6: 3: 1$ ). This selectivity was not so high but acceptable for our synthesis of $\mathbf{1}$. In addition, the conditions as listed in entry $4{ }^{11}$ provided 13 c as the major isomer, and this reversal of selectivity was exactly what we desired for the synthesis of testudinariol B (1'). Structure elucidation of 13a-c was mainly established by NOE experiments, and ${ }^{1} \mathrm{H}-\mathrm{NMR}$ data of $\mathbf{1 3 a}$ and 13 c concerning the cyclopentane portion were in good accord with those reported for natural $\mathbf{1}$ and $\mathbf{1}^{\prime}$, respectively.

The remaining tasks were the preparation of the key intermediate $\mathbf{A}$ and its dimerization or its equivalent operation, which were realized as follows. The hydroxy group of 13a was protected as TBDMS ether ( $99 \%$ ), and the resulting 15a was treated with DDQ ${ }^{12}$ to give $\mathbf{1 5 b}$ in $97 \%$ yield (Scheme 4). Oxidation of $\mathbf{1 5 b}$ with the Dess-Martin periodinane ${ }^{13}$ afforded 16 in $94 \%$ yield. The ketone 16 was employed for the next $(Z)$ selective HWE reaction. As shown in Table 3, treatment with a chiral phosphonoacetate $(S)-\mathbf{1 7}$ developed by Fuji and co-workers ${ }^{14}$ in the presence of NaHMDS ${ }^{15}$ realized the best ( $Z$ )-selectivity ( $E: Z=c a .1: 5$ ), while other commercially available HWE reagents developed by Still $\left[\left(\mathrm{CF}_{3} \mathrm{CH}_{2} \mathrm{O}\right)_{2} \mathrm{P}(=\mathrm{O}) \mathrm{CH}_{2}-\right.$ $\left.\mathrm{CO}_{2} \mathrm{Me}\right]^{16}$ and Ando $\left[(\mathrm{PhO})_{2} \mathrm{P}(=\mathrm{O}) \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{Et}\right]^{17}$ were less selective. It was also noteworthy that the reaction with $(R)-\mathbf{1 7}$ proceeded with the opposite selectivity ( $E: Z=16: 1$ ). It was, to the best of our knowledge, the first example in which Fuji's phosphonoacetate (17) afforded the $(E)$-isomer as major product. The resulting inseparable mixture of $(Z)$ - and $(E)$-18a was reduced with DIBAL-H and purified by $\mathrm{SiO}_{2}$ chromatography to give geometrically pure ( $Z$ )-18b in $78 \%$ yield. The alcohol 18b was then converted to the corresponding bromide 19a ( $93 \%$ ) and sulfone $\mathbf{1 9 b}(87 \%)$ in the conventional manner.

The final challenge was "dimerization". We first attempted to
dimerize 19a by a metal mediated homo-coupling of allylic halide, ${ }^{18}$ and found that the following conditions gave no successful result: Na-naphthalenide in THF at $-78^{\circ} \mathrm{C}$; K-naphthalenide in THF at $-95^{\circ} \mathrm{C} ; \mathrm{BaI}_{2}$, Li-biphenylide in THF at $-78^{\circ} \mathrm{C},{ }^{\mathbf{1 8}}$ etc. However, the methodology employed for the synthesis of limatulones, "sulfone coupling", could be applied successfully to overcome the difficulty. Accordingly, the carbanion derived from 19b by treatment with KHMDS was alkylated with 19 a in the presence of 18 -crown- 6 at $-78^{\circ} \mathrm{C}$ to give the coupling product 20 a in $84 \%$ yield. It was noteworthy that the conventional conditions, $\mathrm{Bu}^{n} \mathrm{Li}$ in THF-HMPA, did not work at all, and the corresponding chloride $(\mathrm{X}=\mathrm{Cl})$ did not react with 19b completely even under our successful conditions. The coupling product 20a was desulfonylated by reduction with $\mathrm{Na}-\mathrm{Hg}$ to afford 20b. Although a small amount of inseparable impurity(ies), which was not the ( $E, Z$ )-isomer, was found to be present, the final deprotection of TBDMS groups made purification possible to give pure (+)-testudinariol A (1) (47\% yield, 2 steps $),[a]_{\mathrm{D}}^{26}=+13\left(c=0.17, \mathrm{CHCl}_{3}\right)\left\{\right.$ ref. $2[a]_{\mathrm{D}}^{25}=+15.2$ $\left.\left(c=0.3, \mathrm{CHCl}_{3}\right)\right\}$. Other physical and spectral data of synthetic $(+)-1$ were in good accord with those reported for the naturally occurring 1 . The overall yield was $5.2 \%$ based on $\mathbf{5}$ in 19 steps.

## Synthesis of testudinariol B (1')

It was obvious that the synthesis of testudinariol B(1') could be accomplished by just substituting the intermediate 13a by 13c. Thus, the intermediate $\mathbf{1 3 c}$ was converted into $\mathbf{1 6}^{\prime}$ in 3 steps ( $90 \%$ yield) (Scheme 5). However, treatment of $\mathbf{1 6}^{\prime}$ with $(S)$ - $\mathbf{1 7}$ in the presence of NaHMDS , the successful combination, gave a roughly $1: 1$ mixture of $(E)$ - and $(Z)-\mathbf{1 8} \mathbf{a}^{\prime}$. This unpredictable decrease in $(Z)$-selectivity led us to examine other $(Z)$-selective HWE reagents again, but only a slight improvement was observed ( $E: Z=c a .4: 6$ ), when Still's phosphonoacetate ${ }^{16}$ was used. The resulting $E$ - $Z$-mixture of $18 \mathbf{a}^{\prime}$ was reduced and the product was purified to give pure $(Z)-\mathbf{1 8 b}^{\prime}(49 \%, 2$ steps $)$.

## Conclusion

In conclusion, the first synthesis of testudinariols A (1) and B (1'), structurally and biosynthetically unusual triterpene alcohols isolated from the marine mollusc Pleurobrancus testudinarius, has been achieved by starting from $(R)$-glycidol. As a result, the proposed unique structures for $\mathbf{1}$ and $\mathbf{1}^{\prime}$ were proved to be correct.

## Stereochemical assignment of 11a and 11b

Stereochemical assignment of the separated diastereomers 11a and 11b was established by ${ }^{1} \mathrm{H}$-NMR analysis at the stage of alcohol $\mathbf{1 4}$ after reduction of ester 11 .
To a stirred solution of $\mathbf{1 1 a}(11 \mathrm{mg}, 28 \mu \mathrm{~mol})$ in hexane $(0.5$ $\mathrm{cm}^{3}$ ) was added DIBAL-H ( $0.95 \mathrm{~mol} \mathrm{dm}^{-3}$ in hexane; $0.20 \mathrm{~cm}^{3}$, 0.19 mmol ) at $-5^{\circ} \mathrm{C}$ under Ar. After having been stirred at $-5^{\circ} \mathrm{C}$ for 30 min , the resulting solution was quenched with MeOH . The mixture was filtered through Celite, and the filtrate was concentrated under reduced pressure. The residue was purified by PTLC to give $\mathbf{1 4 a}(7.6 \mathrm{mg}, 78 \%)$ as a colourless oil. In the same manner as described above, 11b was converted to 14b as a colourless oil.
