The stable monocyclic $\lambda^{4}$-thiabenzenes $\mathbf{6 a}-\mathbf{e}$, which are stabilized with electron-withdrawing substituents such as benzoyl, cyano and alkoxycarbonyl groups, are synthesized in high yields by proton abstraction from the corresponding thiopyranium salts $\mathbf{5 a - e}$ with triethylamine in ethanol. The ylidic properties of the $\lambda^{4}$-thiabenzenes are established based on spectral and chemical evidence. Thermal decomposition of the $\lambda^{4}$-thiabenzenes affords alkyl-rearranged products $\mathbf{7 , 8}$, and $\mathbf{9}$, thienofuran derivatives $\mathbf{1 0}$ (from benzoyl-substituted $\lambda^{4}$-thiabenzenes), and thiophene derivatives 11. A plausible mechanism for the formation of those products is also discussed.

We have reported a series of cyclic sulfur ylides, so-called 'thiabenzenes', in which a sulfur ylide bond participates as part of a cyclic conjugated ring system having six $\pi$-electrons. However, all of these thiabenzenes are benzo-fused derivatives, $1-{ }^{1}$ and 2-thianaphthalenes, ${ }^{2}$ 9-thiaanthracenes, ${ }^{3}$ and 9 -thiaphenanthrenes. ${ }^{4}$ It is of more interest to synthesize monocyclic thiabenzenes in order to investigate in detail the chemistry of the thiabenzene skeleton itself. Attempts for the preparation of monocyclic thiabenzenes have been made by Price ${ }^{5}$ and Hortmann, ${ }^{6}$ but their compounds were too unstable to be isolated. Weber succeeded in stabilization of thiabenzenes as ligands of metal complexes. ${ }^{7}$ Thus, there is no report on the successful isolation of monocyclic thiabenzenes.

We have planned to stabilize the thiabenzenes with an electron-withdrawing group such as a cyano or carbonyl group on the basis of our previous knowledge for the isolation of other benzo-fused thiabenzenes synthesized so far. We report here in detail the synthesis of stable monocyclic thiabenzenes together with their thermal reactions affording some rearranged products including ring contracted ones with an interesting thienofuran skeleton. ${ }^{8}$

## Results and discussion

The synthesis of monocyclic thiabenzenes $\mathbf{6}$ was achieved as illustrated in Scheme 1. Dihydrothiopyrans $\mathbf{2 b}$ e were prepared by the hetero-Diels-Alder reaction of various thioaldehydes, generated in situ from the corresponding Bunte salts and base, with 2,3-dimethylbuta-1,3-dienes according to the procedure of Kirby et al. ${ }^{9}$ The above cycloaddition reaction using buta-1,3diene gas as diene from a cylinder for the synthesis of thiopyran 2a with no alkyl substituents on the hetero ring resulted in a very low yield ( $14 \%$ ) of desired product. Therefore, we tried this synthesis using buta-1,3-diene ${ }^{10}$ generated in situ from the thermolysis of sulfolene in xylene-butanol under an $\mathrm{N}_{2}$ atmosphere to obtain a rather higher yield ( $63 \%$ ) of the thiopyran 2a.

The dihydrothiopyrans 2 were oxidized with $m$-chloroperbenzoic acid (MCPBA) in a cooled dichloromethane solution to afford the corresponding sulfoxides $\mathbf{3}$ in high yields. All of these dihydrothiopyran sulfoxides were obtained as a mixture of cis and trans diastereomers pertaining to the 2 -substituent and sulfoxide oxygen. The structures of cis and trans isomers were assigned by means of ${ }^{1} \mathrm{H}$ NMR spectroscopy, according to

the ordinarily accepted view that relative configuration of the substituents at the 1- and 2-position can be established by assuming that the inductive and deshielding effect of the sulfoxide function on the proton at the 2-position is larger in the trans isomer than in the cis isomer and consequently this proton absorbs at lower field. ${ }^{11,12}$
On refluxing in toluene in the presence of toluene- $p$-sulfonic acid ( $p-\mathrm{TsOH}$ ) catalyst, the dihydrothiopyrans were dehydrated to give the corresponding 2 H -thiopyrans 4 in $68-78 \%$ yield. Alkylation of 6 -aroyl(thiopyrans) $\mathbf{4 a - c}$ with alkyl iodide in the presence of silver tetrafluoroborate or with dialkoxycarbenium tetrafluoroborate in dichloromethane proceeded smoothly to give the corresponding 1 -alkylthiopyranium tetrafluoroborates $\mathbf{5 a}-\mathbf{c}$ in high yield. Methylation of 6-cyano- $\mathbf{4 d}$ and 6 -methoxycarbonyl(thiopyrans) 4 e was accomplished with methyl trifluoromethanesulfonate to give methylthiopyranium salts 5d and $\mathbf{5 e}$ in high yield, respectively, although their alkylation with the combination of methyl iodide and silver tetrafluoroborate proceeded in low yields. Deprotonation of thiopyranium salts 5 with triethylamine in ethanol yielded the corresponding

monocyclic thiabenzenes $\mathbf{6}$ as orange to yellow compounds in $57-100 \%$ yield. These compounds are stable even on exposure to air at room temperature.

The structures of these thiabenzenes were established on the basis of spectral and chemical evidence. The IR spectra of compound 6a shows a strong carbonyl absorption at $1535 \mathrm{~cm}^{-1}$, a lower wavenumber than that of an ordinary aroyl group (1620-1690 $\mathrm{cm}^{-1}$ ). This indicates the delocalization of the carbanion electron through the carbonyl group. The ${ }^{1} \mathrm{H}$ NMR spectrum $\left(\mathrm{CDCl}_{3}\right)$ of $\mathbf{6 a}$ shows a singlet signal at $\delta 2.17$ assignable to S-Me, two doublets at $\delta 5.20$ and 6.90 which are attributed to H-6 and H-3, respectively, and two doublets of doublets at $\delta 5.58$ and 6.98 attributable to $\mathrm{H}-4$ and $\mathrm{H}-5$, respectively. The ${ }^{13} \mathrm{C}$ NMR spectrum $\left(\mathrm{CDCl}_{3}\right)$ of $\mathbf{6 a}$ shows signals at $\delta_{\mathrm{C}} 65.7$ and 85.0 attributable to $\mathrm{C}-2$ and $\mathrm{C}-6$, respectively. These two ${ }^{13} \mathrm{C}$ signals are assigned to $\mathrm{sp}^{3}$ carbons and therefore suggest that a resonance form $\mathbf{6 B}$, in which the ylide carbanion is located on the C-2 position, is an important contributor to the electronic distribution in 6a, as well as a resonance form $\mathbf{6 A}$.

The thiabenzene $\mathbf{6 a}$ was treated with tetrafluoroboric acid in ether to give 5a as the sole product in $84 \%$ yield. This indicates that 6 a reacted with acid in the resonance form $\mathbf{6 A}$ rather than in the resonance form $\mathbf{6 B}$. The spectral and chemical observations described above show that the thiabenzene $\mathbf{6 a}$ has ylidic character. Similar spectral and chemical behaviour was observed for the other thiabenzenes $\mathbf{6 b}, \mathbf{6} \mathbf{b}, \mathbf{6 c}, \mathbf{6 d}$, and $\mathbf{6 e}$ (Experimental section).
Thiabenzenes are very soluble in several solvents such as benzene, ethanol and acetonitrile and can be stored without decomposition at room temperature for several days. We next investigated a thermal reaction of thiabenzenes $\mathbf{6 b}, \mathbf{6} \mathbf{b}^{\prime}$, and $\mathbf{6 d}$ in refluxing solvents. The results are summarized in Scheme 2 and Table 1.

Scheme 2

Thermal decomposition of thiabenzenes proceeded faster in benzene compared with that in acetonitrile and ethanol. This is probably explained by solvation of the polar ylidic structure of thiabenzenes by polar solvents. 2-Aroylthiabenzenes 6b and $\mathbf{6} \mathbf{b}^{\prime}$ in the non-polar solvent benzene underwent thermal rearrangement of 1 -alkyl substituents to give three possible products $\mathbf{7 , 8}$, and $\mathbf{9}$, and thienofuran derivative $\mathbf{1 0}$ (entries 1 and 4). In contrast, they decomposed in the protic solvent ethanol to afford ring-contracted products $\mathbf{1 1}$ as well as two alkyl-migrated products $\mathbf{8}$ and 9 , and thienofuran $\mathbf{1 0}$ (entries 2 and 5). Interestingly, $\mathbf{6 b}$ afforded all of the above five products on refluxing in the polar aprotic solvent acetonitrile for 4 h (entry 3). 6-Cyano-substituted thiabenzene $\mathbf{6 d}$ is less stable than 6 -aroyl-substituted ones and was decomposed on refluxing in solvent within 1 h to give two S-methyl migrated products 7 d and 8d, 11d, and dimerized product 12d in low yield.

The structures of the above products were easily elucidated on the basis of their spectral evidence. For example, structure determination of three methyl-migrated products was made on the basis of ${ }^{1} \mathrm{H}$ NMR spectra which showed allylic coupling ( $J 1.7 \mathrm{~Hz}$ ) between each methyl group and olefinic proton for the compound $\mathbf{7 b}$, and a singlet signal of two methyl groups at the 4 -position at $\delta 1.22$ and allyl coupling between the 5 -methyl and 6 -olefinic proton at $\delta 1.87$ for the compound $\mathbf{8 b}$, and a doublet ( $J 6.8 \mathrm{~Hz}$ ) of the 6-methyl group at $\delta 1.28$ for compound 9 b.
The structure of $\mathbf{1 0 b}$ was also elucidated on the basis of spectral data: the ${ }^{1} \mathrm{H}$ NMR spectrum showing a doublet $(\delta 1.83$, $J 1.7 \mathrm{~Hz}$ ) of the 6-methyl group coupled with the olefinic proton ( $\delta 5.80, J 1.7 \mathrm{~Hz}$ ), and a doublet ( $\delta 1.86, J 1.3 \mathrm{~Hz}$ ) of the 6a-methyl group with a long-range coupling with 3amethine proton ( $\delta 4.64, J 1.3 \mathrm{~Hz}$ ), as well as a lack of both IR absorption and ${ }^{13} \mathrm{C}$ NMR signal due to a carbonyl group in the molecule.

High-resolution mass spectral data indicated a molecular formula of $\mathrm{C}_{15} \mathrm{H}_{15} \mathrm{BrOS}$ for compound 11b. The IR spectrum of compound 11b showed a characteristic absorption band at $1690 \mathrm{~cm}^{-1}$ for the benzoyl group. The ${ }^{1} \mathrm{H}$ NMR spectrum of compound 11b showed a characteristic singlet at $\delta 6.76$ for the thiophene ring proton, and in the phenacyl substituent a methyl doublet $(J 6.8 \mathrm{~Hz})$ at $\delta 1.53$ coupled with a methine proton appearing at $\delta 4.83$.
The complete structure determination of compound 11b was made by comparison with an authentic sample prepared by the route depicted in Scheme 3. The Friedel-Crafts reaction of 3,4-dimethylthiophene $\mathbf{1 3}$ in the presence of anhydrous $\mathrm{ZnCl}_{2}$ with $\alpha$-chloro-4-bromophenacyl methyl sulfide $\mathbf{1 4}$ prepared by chlorination of 4-bromophenacyl methyl sulfide ${ }^{13}$ with NCS afforded 2-substituted 3,4-dimethylthiophene 15 in $39 \%$ yield. Treatment of $\mathbf{1 5}$ with Zn in acetic acid led to the reduction product 16 in $27 \%$ yield, according to the method of Tamura et al. ${ }^{14}$ Deprotonation of $\mathbf{1 6}$ with LDA in THF, followed by addition of methyl iodide, gave the expected compound 11b in $48 \%$ yield.

Finally, we discuss the mechanism for the formation of compounds $\mathbf{1 0}, \mathbf{1 1}$, and 12. The thienofuran $\mathbf{1 0 b}$ was found to
isomerize to the thiophene derivative 11b on storage at room temperature for about one week. The rearranged product 7b was also isomerized partly to the thiophene 11b on storage at room temperature for more than one month. In addition, the isolated product $\mathbf{7 b}$ was subjected to further thermolysis under conditions of refluxing in ethanol for 2.5 h to give $\mathbf{1 0 b}$ in $11 \%$ yield.

Taking account of the above results, the products $\mathbf{1 0}$ and $\mathbf{1 1}$ are considered to be formed by decomposition of the rearranged products 7. In considering the mechanism for the formation of products $\mathbf{1 0}$ and $\mathbf{1 1}$, we propose the formation of the common intermediate $\mathbf{C}$ as a key intermediate from the thiopyran 7 as shown in Scheme 4.

The attack of the lone-pair electrons of sulfur of 7 at the olefinic carbon at the 3-position generates episulfonium ylide intermediate A (path a). The three-membered ring of the intermediate $\mathbf{A}$ is opened to give intermediate $\mathbf{C}$. Enolate ion of the intermediate $\mathbf{C}$ attacks at the 3-position to afford the corresponding compound $\mathbf{1 0}$. The enolate ion abstracts the acidic proton at the 2 -position activated by the adjacent sulfonium ion, followed by tautomerization to furnish the corresponding compound 11. The intermediate $\mathbf{C}$ might be generated by an alternative mechanism involving the thermally provoked electrocyclic ring-opening of the thiopyran 7 to the thiocarbonyl intermediate B (path b), followed by Michael addition of the sulfur atom at an electron-deficient olefinic carbon.

Scheme 3

In order to get information pertaining to the formation of the thiocarbonyl intermediate $\mathbf{B}$, we attempted to trap such a highly reactive thioaldehyde intermediate by the hetero-Diels-Alder reaction with 2,3-dimethylbuta-1,3-diene. However, we could not detect any cycloaddition product. This result suggests the low possibility of path $b$. In addition, higher yields of products 10 and 11 were obtained in polar solvents such as ethanol and acetonitrile than in non-polar solvents as described above, suggesting the preferred formation of polar ylidic intermediate A in path a.

Porter and co-workers also discussed the two plausible intermediates, an episulfonium ylide intermediate and a thiocarbonyl one for the similar thermal ring contraction of 1,2-bis(alkoxycarbonyl)-2H-thiopyran derivatives to thiophenes, and they ruled out the thiocarbonyl intermediate based on the failure of trapping such an intermediate. ${ }^{15}$ We also discussed the similar episulfonium ylide intermediate in the mechanism for the ring contraction of 2-benzothiopyran derivatives to benzothiophenes in our previous report. ${ }^{16}$

Thermal equilibration between the intermediate $\mathbf{C}$ and compound $\mathbf{1 0}$ explains the transformation of $\mathbf{1 0}$ to the compound 11.

Similar thermal decomposition of 2-cyano-substituted derivative 7d forms the corresponding intermediate $\mathbf{C}^{\prime}$, which isomerizes only to compound 11d, with no cyclization to the bicyclic product corresponding to compound 10, probably because of the linear structure of the heterocummulene moiety of the estimated intermediate $\mathbf{C}^{\prime}$.

The formation of product $\mathbf{1 2}$ might be explained by a mechanism involving self-coupling of the thiopyranyl radical intermediate formed by homolytic demethylation of the thiabenzene 6d. Such a homolytic dealkylation has been often observed in the thermal decomposition of sulfonium salts. ${ }^{17}$

## 2-[4-Bromobenzoyl(methylsulfanyl)methyl]-3,4-dimethylthiophene 15

NCS (452 mg, 3.38 mmol ) was added to an ice-cooled solution of 4-bromophenacyl methyl sulfide ${ }^{13}$ ( $798 \mathrm{mg}, 3.26 \mathrm{mmol}$ ) in tetrachloromethane ( $15 \mathrm{~cm}^{3}$ ) with stirring. The mixture was stirred for 2 h and the precipitate was filtered off. The filtrate was concentrated under reduced pressure and dichloromethane $\left(8 \mathrm{~cm}^{3}\right)$ and 3,4-dimethylthiophene ${ }^{18} \mathbf{1 3}(1.83 \mathrm{~g}, 16.3 \mathrm{mmol})$ were added to the residue. This mixture was ice-cooled and zinc chloride ( $311 \mathrm{mg}, 2.28 \mathrm{mmol}$ ) was added with stirring. After the reaction mixture had been stirred for 40 min , water was added and the organic layer was separated, washed with water, and dried $\left(\mathrm{MgSO}_{4}\right)$. Evaporation of the mixture gave a crude oil, which was chromatographed on silica gel with hexane-ethyl acetate ( $100: 1$ ) to afford $15(448 \mathrm{mg}, 38.7 \%)$ as a pale yellow oil; $v_{\text {max }}($ neat $) / \mathrm{cm}^{-1} 1675(\mathrm{CO}) ; \delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 2.05,2.12$ and 2.15 (each $3 \mathrm{H}, \mathrm{s}, \mathrm{Me}$ ) and $5.67(1 \mathrm{H}, \mathrm{s}, \mathrm{CH}), 6.89(1 \mathrm{H}$, br s, $5-\mathrm{H})$ and 7.58 and 7.87 (each $2 \mathrm{H}, \mathrm{d}, J 8.5, \mathrm{ArH}) ; \delta_{\mathrm{C}}\left(\mathrm{CDCl}_{3}\right) 12.9(\mathrm{q})$, 13.6 (q), 15.1 (q), 47.7 (d), 121.3 (d), 128.4 (s), 130.2 (d), 130.7 (s), 131.9 (d), 134.2 (s), 135.2 (s), 137.5 (s) and 191.4 (s); $m / z 354\left(\mathrm{M}^{+}\right)$(Found: $\mathrm{M}^{+}, 353.9728 . \mathrm{C}_{15} \mathrm{H}_{15} \mathrm{BrOS}_{2}$ requires $M$, 353.9747).

## 2-(4-Bromophenacyl)-3,4-dimethylthiophene 16

Zinc dust ( $1.4 \mathrm{~g}, 21 \mathrm{mmol}$ ) was added to a solution of $\mathbf{1 5}$ $(350 \mathrm{mg}, 0.99 \mathrm{mmol})$ in acetic acid $\left(5 \mathrm{~cm}^{3}\right)$ and the mixture was stirred at $100^{\circ} \mathrm{C}$ for 1 h . The cooled reaction mixture was poured into water and extracted with dichloromethane. The extract was washed with water, dried $\left(\mathrm{MgSO}_{4}\right)$, and evaporated. The oily residue was purified by PLC on silica gel with hexaneethyl acetate ( $40: 1$ ) to afford $\mathbf{1 6}(81 \mathrm{mg}, 27 \%)$ as a pale orange oil; $v_{\text {max }}$ (neat)/cm ${ }^{-1} 1690(\mathrm{CO}) ; \delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 2.04(3 \mathrm{H}, \mathrm{s}, \mathrm{Me})$, $2.06(3 \mathrm{H}, \mathrm{br} \mathrm{s}, \mathrm{Me}), 4.32\left(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}_{2}\right), 6.79(1 \mathrm{H}, \mathrm{s}, 5-\mathrm{H})$ and 7.60 and 7.86 (each $2 \mathrm{H}, \mathrm{d}, J 8.5, \mathrm{ArH}) ; \delta_{\mathrm{C}}\left(\mathrm{CDCl}_{3}\right) 12.5$ (q), 15.3 (q), 38.3 (t), 118.9 (d), 128.3 (s), 128.4 (s), 130.0 (d), 131.9 (d), 135.0 (s), $135.2(\mathrm{~s}), 137.9(\mathrm{~s})$ and $195.0(\mathrm{~s}) ; m / z 308\left(\mathrm{M}^{+}\right)$(Found: $\mathrm{M}^{+}, 307.9845 . \mathrm{C}_{14} \mathrm{H}_{13}$ BrOS requires $M, 307.9870$ ).

## 2-[1-(4-Bromobenzoyl)ethyl]-3,4-dimethylthiophene 11b

Butyllithium ( $1.62 \mathrm{~mol} \mathrm{dm}{ }^{-3}$ solution in hexane; $0.25 \mathrm{~cm}^{3}$, 0.41 mmol ) was added with stirring to a solution of diisopropylamine $\left(0.1 \mathrm{~cm}^{3}, 0.41 \mathrm{mmol}\right)$ in dry THF $\left(5 \mathrm{~cm}^{3}\right)$ at $-30^{\circ} \mathrm{C}$ under nitrogen. After 30 min , a solution of $16(58 \mathrm{mg}, 0.19$ $\mathrm{mmol})$ in dry THF $\left(2 \mathrm{~cm}^{3}\right)$ was added in a stream of nitrogen to
the above solution at $-70^{\circ} \mathrm{C}$. After the mixture had been stirred for 50 min at the same temperature, methyl iodide $\left(0.1 \mathrm{~cm}^{3}, 1.6 \mathrm{mmol}\right)$ was added and the mixture was allowed to warm to room temperature. Saturated aq. $\mathrm{NH}_{4} \mathrm{Cl}$ was added and the mixture was extracted with dichloromethane. The extract was washed with water, dried $\left(\mathrm{MgSO}_{4}\right)$, and evaporated to dryness. The residual oil was subjected to PLC on silica gel with hexane-ethyl acetate ( $13: 1$ ) to afford 11b ( 29 mg , $48 \%$ ) as a colourless oil. This compound showed the same spectral properties as those of compound 11b obtained from thermolysis of $\mathbf{6 b}$.
