Enamino acids derived from 1,2-dimethylaminomethylene- or 1,2-hydroxymethylene-carbonyl compounds and amino acids undergo a decarboxylative cyclisation to pyrroles, isoindoles and other fused pyrroles. A two atom ring expansion occurs preferentially with enamino acids from cyclohexane-1,3-diones and $\alpha$-alkyl- $\alpha$-amino acids leading to oxocino $[2,3-c]$ pyrroles.

## Introduction

The pyrrole unit ${ }^{1}$ occurs in a range of naturally occurring compounds, pharmaceutical products and polymers. ${ }^{2}$ The synthesis of this ring system has been widely investigated and has featured in a number of reviews. ${ }^{3,4}$ Nevertheless, ring syntheses of pyrroles unsubstituted at the 2- and 5-positions and routes which involve formation of the $\mathrm{C}-2-\mathrm{C}-3$ bond are uncommon. ${ }^{4 a}$ Probably the single most convenient entry to compounds of this type involves the condensation of $\alpha, \beta$-unsaturated ketones, esters and nitriles and nitroalkenes with tosylmethyl isocyanide (TosMIC) and related compounds. ${ }^{4 b}$ Several routes to pyrroles involve the reaction of 1,3dicarbonyl compounds and $\alpha$-amino acids, but in all of these examples a carboxylate function is retained in the pyrrole. ${ }^{5}$ Since its discovery in 1973 by Zav'yalov et al. ${ }^{6}$ the efficient synthesis of pyrroles based on the acetic anhydride-promoted cyclisation of the salt of an enamino acid (Scheme 1) has

Scheme 1 Reagents and conditions: (i) $\mathrm{Ac}_{2} \mathrm{O}, \Delta$.
been rarely used. ${ }^{7}$ We now report the synthesis of some novel substituted pyrroles and fused analogues through the application of this methodology and describe a unique ring expansion reaction that affords the oxocino[2,3-c]pyrrole system.

## Discussion

Dimethylaminomethylene carbonyl compounds $\mathbf{1 a}^{8}$ and $\mathbf{1 b}{ }^{9}$ were obtained by standard protocols. Their additionelimination reaction with DL-2-phenylglycine and glycine in aqueous ethanol containing sodium acetate gave the enamino acids 2a-c in high yield (Scheme 2). The ${ }^{1} \mathrm{H}$ NMR spectrum of 2a indicated that an unequal mixture ( $c a .3: 1$ ) of $E$ - and $Z$ isomers had been isolated. In the former, the NH proton is strongly H-bonded to the acetyl carbonyl resulting in a low field signal ( $\delta 11.68$ ). In the $Z$-isomer intramolecular H -bonding is weaker because of participation of the ester group as evidenced by the upfield shift of this signal to $\delta 10.06$.

A deep red colour was instantaneously produced when the enamino acids $2 \mathrm{a}-\mathrm{c}$ were heated with acetic anhydride contain-

ing triethylamine and this was accompanied by the vigorous evolution of $\mathrm{CO}_{2}$ (lime water bubbler) as the internal reaction temperature reached reflux. After ca. 30 minutes, the reaction mixture was cooled and subjected to an aqueous work-up. TLC examination of the crude reaction mixtures revealed the presence of a fast running major component contaminated with dark base line material rendering initial purification by flash chromatography easy.

The cyclisation of the isomeric enamino acids 2 a proceeded with the expected regioselectivity of cyclisation on to the more electrophilic ketonic carbonyl group rather than the ester function to afford a single pyrrole, 3a, confirmed by the presence of signals in its ${ }^{1} \mathrm{H}$ NMR spectrum associated with the ethyl ester moiety. The pyrrole ring proton resonates significantly downfield at $\delta 7.93$ as a consequence of the adjacent ester function; the 4-methyl group and the N -acetyl function are observed at $\delta 2.08$ and $\delta 2.21$, respectively.

Of particular note is the relatively efficient preparation (ca. $40 \%$ overall yield) of the 2,5-unsubstituted pyrrole $\mathbf{3 b}$. Existing routes to compounds of this type are often laborious and low yielding. ${ }^{3 c, f, h, 4 a}$ The ${ }^{1} \mathrm{H}$ NMR spectrum of this compound displayed the expected singlets at $\delta 7.25$ and 7.78 for $5-\mathrm{H}$ and 2-H respectively.

Cyclohexane-1,3-dione and dimedone were converted according to literature procedures into the respective enamino ketones $\mathbf{4 a}{ }^{10}$ and $\mathbf{4 b},{ }^{11}$ which were reacted with a range of $\alpha$-amino acids according to the above method to afford the enamino acids 5a-e (Schemes 3 and 4). and elimination of amino acids to 5,5-dimethyl-2-(dimethy-aminomethylene)cyclohexane-1,3-dione $\mathbf{4 b}$ has been advocated as an amino protection-deprotection sequence useful in solid phase synthesis. ${ }^{12}$ The cyclisation of $\mathbf{5 a} \mathbf{-}$ was then investigated. Heating the enamino acids derived from DL-2-phenylglycine ( 5 a and 5 c ) with acetic anhydride containing $\mathrm{Et}_{3} \mathrm{~N}$ gave the expected dihydroisoindoles $\mathbf{6 a}$ and $\mathbf{6 b}$, respectively. The ${ }^{1} \mathrm{H}$ NMR spectra of these compounds displayed a singlet at $c a . \delta$ 7.1 for the pyrrole ring proton. The remaining carbonyl function of the starting dione had been converted to the enol acetate as indicated by the presence of a signal at $\sim \delta 5.4$ for the alkenic proton and at $\sim \delta 2.2$ for the OAc group. Compound $\mathbf{6 a}$ was efficiently de-acetylated on heating in aqueous acetic acid containing conc. HCl to afford $7(92 \%)$. The presence of a broad singlet at $\delta 9.7$ for the pyrrole NH and the absence of the signal for the alkenic proton associated with the enol acetate unit in the ${ }^{1} \mathrm{H}$ NMR spectrum of 7 indicated that both acetyl functions had been removed. The ${ }^{13} \mathrm{C}$ NMR of this compound displayed a low field signal at $\delta 196.9$ for the carbonyl group carbon.

In marked contrast to our observation noted for the cyclisation of the enamino acids $\mathbf{2 a - c}$ and 5a,c, only slight evolution of $\mathrm{CO}_{2}$ was observed when enamino acids $\mathbf{5 b}, \mathbf{d}$, and e were heated in acetic anhydride containing $\mathrm{Et}_{3} \mathrm{~N}$, suggesting that some other reaction sequence had occurred (Scheme 4),
although the ${ }^{1} \mathrm{H}$ NMR spectrum of the product derived from 5b appeared to be in agreement with structure 8a. However, HRMS and elemental analysis data did not support this structure, instead suggesting that the molecule contained an additional $\mathrm{CO}_{2}$. The presence of a third low field signal between $\delta 168-169$ in the ${ }^{13} \mathrm{C}$ NMR spectrum confirmed these data; this chemical shift range is indicative of a carboxylate-type carbon. Attempts to obtain a crystal structure of this compound were unsuccessful since the compound decomposed during repeated recrystallisation.

We next turned our attention to the product obtained from the cyclisation of $\mathbf{5 d}$. The ${ }^{1} \mathrm{H}$ NMR spectrum of this compound recorded at ambient temperature $\left(24^{\circ} \mathrm{C}\right)$ was uninformative since many signals in the range $\delta 0.5-3.5$ were poorly resolved (Fig. 1), but a signal at $\delta 7.7$, a chemical shift that is comparable

Fig. 1 Variable temperature ${ }^{1} \mathrm{H}$ NMR spectra ( $\delta 0.5-3.5$ ) for oxocinopyrrole 9b.
to that of $2-\mathrm{H}$ in $\mathbf{3 a - c}$, was clear. However, dramatic improvements in resolution were achieved by recording the spectrum at either elevated $\left(55^{\circ} \mathrm{C}\right)$ or reduced $\left(-20^{\circ} \mathrm{C}\right)$ temperature (Fig. 1) indicating that the molecule is undergoing conformational interconversion. Once again the ${ }^{1} \mathrm{H}$ NMR spectrum of this product appeared to suggest that isoindole $\mathbf{8 b}$ had been isolated, though this data was again incompatible with other spectroscopic evidence. The ${ }^{13} \mathrm{C}$ NMR spectrum displayed a signal for an additional carbon atom at $c a . \delta 169$. Infrared spectroscopy was inconclusive with only two bands present in the $\mathrm{C}=\mathrm{O}$ stretching region. However, X-ray crystallography of this compound indicated the oxocino[2,3-c]pyrrole structure $\mathbf{9 b} .{ }^{13}$ With the structure of $\mathbf{9 b}$ to hand, it is evident that the product from the cyclisation of $\mathbf{5 b}$ is the related acetoxy oxocinopyrrole 9 a. It is noteworthy that the ${ }^{1} \mathrm{H}$ NMR spectrum of $9 \mathbf{a}$ is well resolved at ambient temperature as a consequence of the rigidity imparted into the oxocine ring by the enol acetate function. The absence of this structural feature in 9b allows

Scheme 4 Reagents and conditions: (i) $\mathrm{Ac}_{2} \mathrm{O}, \mathrm{Et}_{3} \mathrm{~N}, \Delta$.
broadening of the signals in its ${ }^{1} \mathrm{H}$ NMR spectrum as a consequence of the oxocine ring existing in equilibrium between several conformers. ${ }^{14}$

The low temperature ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{9 b}$ merits some further comment. The four methylene protons (3-C and 5-C) are non-equivalent and each gives rise to a doublet with $J 12.3$ Hz . In order to confirm this coupling a ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY experiment at $-40^{\circ} \mathrm{C}$ was recorded (Fig. 2). This revealed that the

Fig. 2 Low temperature $\left(-40{ }^{\circ} \mathrm{C}\right){ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectrum for oxocinopyrrole 9b.
12.3 Hz coupling was not due to a geminal interaction but was instead a consequence of one of the $3-\mathrm{H}$ protons coupling to one of the $5-\mathrm{H}$ protons, i.e. 4 -bond coupling. The magnitude of this coupling in $9 \mathbf{b}$ is quite unusual since ${ }^{4} J$ is typically $1-2$ Hz. ${ }^{15 a}$ However, substantially larger ${ }^{4} J$ coupling constants have been reported for rigid bicyclic systems where more than one coupling pathway may operate. ${ }^{15 b}$

In order to confirm this unexpected long-range relationship between 3- and $5-\mathrm{H}$ we selectively decoupled the doublet at $\delta 2.28(3-\mathrm{H})$. Whilst some loss of resolution of the doublet at $\delta 2.38$ was observed due to the decoupling pulse employed, more significantly the signal at $\delta 2.93$ resolved into a singlet confirming the coupling arrangement (Fig. 3).

Fig. 3 Low temperature $\left(-40^{\circ} \mathrm{C}\right){ }^{1} \mathrm{H}$ NMR homo decoupling of the doublet at $\delta 2.28$ in oxocinopyrrole $9 \mathbf{9 b}$.

Unfortunately the product derived from heating enamino acid 5 e, derived from $\mathbf{4 b}$ under the standard conditions, decomposed on storage at room temperature.

A possible mechanism for the formation of the isoindoles $\mathbf{8}$ and oxocinopyrroles 9 is outlined in Scheme 5. We favour pathways involving the intermediacy of a ketene since their formation via elimination from mixed anhydrides is especially facile under basic conditions, many examples of this for $N$ and $O$ - linked alkanoic acids have been documented. ${ }^{16 a}$ The acylation of $N$-substituted amino acids proceeds with cyclodehydration to provide mesoionic 1,3-oxazolium-5-olates (münchnones) ${ }^{16 b}$ and evidence has accrued that these are tautomeric with $N$-acyl ketenes. ${ }^{16 c}$ The mesoionic heterocycle $\mathbf{1 0}$ may react by two distinct pathways to afford $\mathbf{8}$. We propose that, when $\mathrm{R}=$ phenyl, the extended conjugation imparts

Scheme 5
stability to the münchnone tautomer which then attacks the proximal $\mathrm{C}=\mathrm{O}$ group. The alkoxide species thus generated forms the lactone 11 with concomitant oxazole ring cleavage. Alternatively, cyclisation of the valence tautomer 12 (path a) provides an oxazepine intermediate which contracts to 11. It is pertinent to note that a similar dipolar species, a dioxepine, has been invoked in the $\mathrm{Ac}_{2} \mathrm{O}$-mediated cyclisation of $o$-acylphenoxyalkanoic acids to benzofurans. ${ }^{16 d}$ Cycloreversion of $\mathrm{CO}_{2}$ from 11 and subsequent $O$-acylation completes the route to the dihydroisoindoles 8 . Conversely, when $\mathrm{R}=$ alkyl, the münchnone 10 undergoes ring-chain tautomerism to the $N$-acyl ketene 12. Intramolecular acylation of the enamine function affords the spirocycle 13 (path b). Oxetane ring formation and subsequent ring cleavage of $\mathbf{1 4}$ effects the ring expansion to the oxocinopyrrole system 9 .
It was of interest to explore the versatility of this route for the formation of other fused pyrrole containing systems. Thus indan-1-one and indane-1,3-dione were readily converted into the dimethylaminomethylene ketones $\mathbf{1 5 a},{ }^{17} \mathbf{b}^{10}$ respectively. Treatment with an ethanolic solution of an $\alpha$-amino acid containing sodium acetate gave the respective enamino acids 16a,b in high yield (Scheme 6). Unfortunately attempts to

Scheme 6 Reagents and conditions: (i) 1.05 eq. $\alpha$-amino acid, 1.05 eq. $\mathrm{NaOAc} \cdot 3 \mathrm{H}_{2} \mathrm{O}$, aq. $\mathrm{EtOH}, \Delta$.
cyclise these compounds in the usual manner gave only tarry multicomponent reaction mixtures from which no indeno[c]fused pyrroles $\mathbf{1 7}$ could be isolated. It is possible that the postulated intermediate in the formation of 17, a tricyclic 5-5-4 system (cf. 11), is too strained to form thus preventing the cycloreversion of the lactone ring that ultimately affords the product.
2-Hydroxymethylene-1-tetralone 18a is readily available by the formylation of 1 -tetralone. ${ }^{18}$ Treatment of this $\beta$-dicarbonyl compound with glycine according to the above procedure gave enamino acid 19a as bright yellow microcrystals in $74 \%$ yield. Enamino acids 19b-e were similarly obtained from the appropriate amino acids (Scheme 7). With the exception of 19a from which only a small amount of 1-tetralone could be isolated from the tarry residue, the cyclisation of these enamino acids proceeded smoothly to give the benzo $[e]$ isoindoles $\mathbf{2 0 b}-\mathbf{e}$.

The cyclisation of 19d, derived from dL-methionine sulfoxide, yielded two products that were separated by elution from silica. The less polar component was characterised as acetoxymethylene-1-tetralone 21. ${ }^{19}$ The nitrogen containing product was not the expected benzo [e]isoindole containing the $\left(\mathrm{CH}_{2}\right)_{2} \mathrm{~S}(\mathrm{O}) \mathrm{CH}_{3}$ group but was instead 20d, arising from a regiospecific Pummerer rearrangement ${ }^{20}$ of the $\left(\mathrm{CH}_{2}\right)_{2} \mathrm{~S}(\mathrm{O}) \mathrm{CH}_{3}$ function under the reaction conditions to provide the $\left(\mathrm{CH}_{2}\right)_{2} \mathrm{SCH}_{2} \mathrm{OAc}$ side-chain. The ${ }^{1} \mathrm{H}$ NMR spectrum of this compound displayed singlets at $\delta 2.09$ and 2.55 for the $O$ - and

$N$-acetyl groups and a further singlet at $\delta 5.29$ was assigned to the methylene function of the $O, S$-acetal.

We next explored the application of enamino acids $\mathbf{1 9 f}, \mathbf{g}$ derived from the tetralone homologue, 2-hydroxymethylene-1benzosuberone 18b, ${ }^{21}$ for the formation of further fused pyrrroles (Scheme 7). Both $\mathbf{1 9 f}$ and $\mathbf{1 9 g}$ cyclised smoothly to afford the expected pyrroles $\mathbf{2 0 f}, \mathbf{g}$ in good yield.

From our research projects on chromanones and thiochromanones we had access to a range of 3 -hydroxymethylene(thio)chromanones 18c-f. ${ }^{22,23}$ The enamino acids, 19h and 19i, derived from glycine and the 3-hydroxymethylenebenzopyrans 18c and 18d respectively, cyclised to give the benzopyrano[3,4$c]$ pyrroles 20 h and i . The benzopyrano $[3,4-c]$ pyrrole ring system has recently been accessed by the photogeneration of radicals from $\alpha$-stannyl ethers and their conjugate addition to enones, ${ }^{24}$ through the displacement of the iron residue in $4-\left[\eta^{5}\right.$-cyclopenta-dienyl(dicarbonyl)iron]- 2 H -chromene-3-carbaldehyde with primary amines ${ }^{25}$ and by the Fischer-Fink reaction of 4-chloro3 -formylcoumarins with amino acid esters. ${ }^{26}$ The benzo-pyrano[3,4-c]pyrrole unit has found application in photocrosslinkable polymers ${ }^{27}$ and as the structural unit in some methine dyes. ${ }^{28}$ The enamino acids $\mathbf{1 9 j}-\mathbf{n}$, derived from hydroxymethylenethiochromanones 18e and $\mathbf{f}$, gave mixed results on heating in $\mathrm{Ac}_{2} \mathrm{O}-\mathrm{Et}_{3} \mathrm{~N}$. Compounds 191 and $\mathbf{m}$ obtained from the 2,2-dimethyl-3-hydroxymethylenethiochromanone $\mathbf{1 8 f}$ gave the expected benzothiopyrano[3,4-c]pyrroles $\mathbf{2 0 k}$ and $\mathbf{I}$ in $c a$. $50 \%$ yield and constitutes the first synthesis of this ring system.

However, we were unable to obtain any benzothiopyrano[3,4-c]pyrrole from the attempted cyclisation of enamino acid $19 n$ which was derived from dL-alanine and 18f. The enamino acid 19j derived from glycine and the 3-hydroxymethylene-2methylthiochromanone 18e also failed to afford any isolable pyrrole, although, that derived from 18e and DL-2-phenylglycine ( $\mathbf{1 9 k}$ ) gave the pyrrole $\mathbf{2 0 j}$ in a respectable $64 \%$ yield.

1-Dimethylaminomethylene-2-tetralone 22 was prepared by heating 2 -tetralone in $\mathrm{N}, \mathrm{N}$-dimethylformamide dimethyl acetal. ${ }^{29}$ Subsequent reaction with DL-2-phenylglycine in aqueous ethanol containing $\mathrm{NaOAc} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ gave the enamino acid $\mathbf{2 3}$ in $53 \%$ yield. Cyclisation of $\mathbf{2 3}$ using the standard protocol gave the isomeric 3-phenylbenzo $[e]$ isoindole 24 after elution from silica in $56 \%$ yield.

The ${ }^{1} \mathrm{H}$ NMR spectra of the fused pyrroles and isoindoles $\mathbf{2 0}$ merit some comment. For the 1 -alkyl substituted compounds $\mathbf{2 0 c}, \mathbf{d}, \mathbf{e}$ and $\mathbf{g}$ the pyrrole ring proton ( $3-\mathrm{H}$ ) resonates at $c a . \delta$ 6.9. This signal is shifted downfield by $c a .0 .3 \mathrm{ppm}$ on replacement of the alkyl group by a phenyl ring e.g. 20b,j and $\mathbf{1}$. The pyrrole ring proton $(1-\mathrm{H})$ of the isomeric 3-phenyl substituted isoindole 24 appears further downfield at $\delta 7.64$. Noticeably $9-\mathrm{H}$ resonates at $\delta 7.54$ in $\mathbf{2 4}$ but is shifted significantly upfield to $\delta 6.69$ in 20b. It would appear that $9-\mathrm{H}$ lies in the shielding zone of the 1 -phenyl substituent, suggesting that the disposition of the phenyl ring must approach perpendicularity with respect to the major plane of the molecule. A similar situation has been previously noted for some related benzothiopyranopyrazoles. ${ }^{23}$ In the ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{2 0 d}$ and $\mathbf{2 0 j} \mathbf{3 - H}$ appeared as a doublet with $J=1.0 \mathrm{~Hz}$ as a result of allylic coupling to $4-\mathrm{H}$. In the case of 1,3 -unsubstituted fused pyrroles, (20a, 20f, 20h, 20i, $\mathbf{2 0 k}$ ) the signals from 1-H and 3-H overlap with the aromatic signals.

The generality of this pyrrole ring synthesis was investigated further by reacting hydroxymethylene 18c with 2 -aminoacetonitrile which under routine conditions gave the enamino nitrile $\mathbf{2 5}$ in high yield. However, attempts to cyclise this nitrile to the pyrrolecarbonitrile 26 failed.
It is noteworthy that the formation of the pyrroles 3 , isoindoles $\mathbf{6}$ and the fused analogues 9,20 and $\mathbf{2 4}$ is chemoselective, and in no instances did we observe the presence of any $\alpha$-amino ketones resulting from a Dakin-West reaction. ${ }^{30}$ Furthermore the formation of the oxocinopyrroles 9 only occurs with the combination of an $\alpha$-alkyl- $\alpha$-amino acid and a cyclohexane-1,3-dione; replacement of either one of these components results in the formation of the pyrrole or isoindole.

We next explored the possibility of a thermal cyclisation of enamino acid 19h. Heating 19h in bromobenzene effected the gradual evolution of $\mathrm{CO}_{2}$ and resulted in the formation of two products that were resolved by flash chromatography (Scheme 8). The less polar fraction was characterised as the 3-(methylaminomethylene)chromanone 27 formed through decarboxylation of the glycine residue. In the ${ }^{1} \mathrm{H}$ NMR spectrum of this compound the NH proton resonated at $\delta 10.23$ as a consequence of intramolecular H -bonding to the carbonyl

Scheme 8 Reagents and conditions: (i) $\mathrm{PhBr}, \Delta$ (ii) $\mathrm{PTAD}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, rt.
function and the alkenyl proton appeared at $\delta 6.83$, typical for such aminomethylene compounds. ${ }^{31}$ The more polar fraction was characterised as 3-isopropenylchromone 28 and had physical and spectroscopic properties comparable with authentic material. ${ }^{22}$ The formation of 3-alkenyl- chromones ${ }^{22}$ and thiochromones ${ }^{23}$ by the rearrangement of 3-hydroxymethylene(thio)chromanones has been reported by us previously though in both instances the presence of acid was used to effect the rearrangement. The alkenylchromone $\mathbf{2 8}$ was subsequently reacted with 4 -phenyl-1,2,4-triazoline-3,5-dione ${ }^{32}$ (PTAD) in dichloromethane at room temperature to afford the novel fused tetracycle 29 in $92 \%$ yield. The ${ }^{1} \mathrm{H}$ NMR spectrum of 29 displayed an AB system for $5-\mathrm{H}$ with $J=17.7 \mathrm{~Hz}$. The methine proton, $12 \mathrm{a}-\mathrm{H}$, appeared as a singlet at $\delta 6.83$, a feature that confirmed that the double bond had not migrated into the pyran ring, a process that has been observed with cycloadditions to 2 -styrylchromones. ${ }^{33}$ 8-H resonates furthest downfield of the aromatic signals due to its proximity to the anisotropic carbonyl group at C-7.

In conclusion, this route to the pyrrole system is highly versatile, since it offers potential for the formation of novel 2,5-unsubstituted pyrroles when glycine is employed as the $\alpha$-amino acid, is compatible with a range of $\alpha$-amino acids and $\alpha$-hydroxy- and $\alpha$-amino-methylene carbonyl compounds, is applicable to the synthesis of 3-hydroxypyrrole derivatives, isoindoles and fused pyrrole derivatives, and provides facile access to the novel oxocino[2,3-c]pyrrole ring system by a two atom ring expansion process.

## Experimental

Melting points were determined in capillary tubes and are uncorrected. Distillations were performed using a Kugelrohr (Buchi GKR-50 Glass Tube Oven) and all boiling points quoted relate to the oven temperature at which the distillation commenced. Fourier transform infrared spectra were recorded on a Mattson Polaris spectrophotometer. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on either a Bruker WM 250 or Avance 400 MHz or a JEOL $\lambda$ series 400 MHz instrument for solutions in $\mathrm{CDCl}_{3}$ unless stated otherwise; coupling constants $J$ are given in Hz . Flash chromatographic separations were performed on chromatography silica as supplied by Fluorochem Ltd. (MPD 40-63 $)$ according to the published procedure. ${ }^{34}$

## General method for the preparation of carboxymethylaminomethylene derivatives

The dimethylamino- and hydroxy-methylene compound (15 mmol ) was dissolved in ethanol ( $35 \mathrm{~cm}^{3}$ ) and a solution of the amino acid ( 18 mmol ) and sodium acetate trihydrate ( 18 mmol ) in the minimum volume of aqueous ethanol to effect complete dissolution was added in a single portion. The resulting
solution was refluxed for 4 h . and then reduced in volume to $c a .25 \mathrm{~cm}^{3}$. The product was precipitated by the addition of ice-water $\left(40 \mathrm{~cm}^{3}\right)$ and the pH of the solution adjusted to $\sim 6$ with dilute hydrochloric acid ( 2 M , aq.). The precipitate was collected by vacuum filtration, washed thoroughly with cold water and air-dried. The following compounds were obtained by this protocol.

1 DL-( $E$ )- and DL-( $Z$ )-Ethyl 2-(1-carboxy-1-phenylmethyl-aminomethylene)-3-oxobutanoate 2a. General method for the cyclisation of the carboxymethylaminomethylene derivatives
The carboxymethylaminomethylene derivatives ( 10 mmol ) and triethylamine ( $10 \mathrm{~cm}^{3}$ ) were refluxed in acetic anhydride ( 30 $\mathrm{cm}^{3}$ ) until the vigorous evolution of $\mathrm{CO}_{2}$ (limewater bubbler) ceased, after approximately 30 min , and then allowed to cool to RT. The resulting dark red solution was poured into water $\left(400 \mathrm{~cm}^{3}\right)$ and stirred for 1 h and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(4 \times 50$ $\mathrm{cm}^{3}$ ). The combined organic extracts were washed with water $\left(2 \times 100 \mathrm{~cm}^{3}\right)$, saturated $\mathrm{NaHCO}_{3}$ solution $\left(5 \times 50 \mathrm{~cm}^{3}\right)$ and finally with water $\left(100 \mathrm{~cm}^{3}\right)$. Removal of the dried $\left(\mathrm{Na}_{2} \mathrm{SO}_{4}\right)$ solvent afforded a red-brown oil which either crystallised on standing or was eluted from silica. The following compounds were isolated by this protocol.

[^1]1 Ethyl 1-acetyl-4-methyl-5-phenylpyrrole-3-carboxylate 3a. The bromobenzene was removed under reduced pressure and the viscous brown residue eluted with $40 \%$ EtOAc in hexane to afford two fractions. Fraction 2. 3-Isopropenyl-4H-1-benzopyran-4-one 28 from light petroleum (bp $40-60^{\circ} \mathrm{C}$ ) (yield $36 \%$ ), mp 57.5-59.0 ${ }^{\circ} \mathrm{C}$ [lit. ${ }^{22} \mathrm{mp} 57.0-59.0$ $\left.{ }^{\circ} \mathrm{C}\right] ; v_{\text {max }}$ (Nujol) $1639 \mathrm{~cm}^{-1}$; $\delta_{\mathrm{H}} 2.10(3 \mathrm{H}, \mathrm{s}, \mathrm{Me}), 5.16(1 \mathrm{H}, \mathrm{m}$, isopropenyl-H), $5.45(1 \mathrm{H}, \mathrm{m}$, isopropenyl-H), $7.37(2 \mathrm{H}, \mathrm{m}$, $\mathrm{Ar}-\mathrm{H}), 7.60(1 \mathrm{H}, \mathrm{m}, \operatorname{Ar}-\mathrm{H}), 7.88(1 \mathrm{H}, \mathrm{s}, 2-\mathrm{H}), 8.22(1 \mathrm{H}, \mathrm{dd}$, J8.3, 1.9, $5-\mathrm{H}$ ).

A solution of the aforegoing 3-isopropenyl-4H-1-benzopyran-4-one $28(10 \mathrm{mmol})$ was dissolved in dichloromethane $\left(25 \mathrm{~cm}^{3}\right)$. PTAD [prepared according to the procedure described by Moriarty et al. ${ }^{35}$ ] ( 10 mmol ) in dichloromethane $\left(30 \mathrm{~cm}^{3}\right.$ ) was added dropwise with stirring. The red colour of the PTAD was instantly discharged and after stirring for 5 h the precipitated cycloadduct was collected by vacuum filtration and washed thoroughly with ether to afford analytically pure 6-methyl-2-phenyl-2,3,5,12a-tetrahydro-1H,7H-[1]benzopyrano-[2,3-c][1,2,4]triazolo[1,2-a]pyridazine-1,3,7-trione 29 as colourless microcrystals (yield 92\%), mp 189.0-205.0 ${ }^{\circ} \mathrm{C}$ (decomp.); $v_{\max }$ (Nujol) 1770, 1715, 1675, $1635 \mathrm{~cm}^{-1} ; \delta_{\mathrm{H}}$ (DMSO-d $\mathrm{d}_{6}$ ) $2.35(3 \mathrm{H}, \mathrm{s}, 6-\mathrm{Me}), 4.41(1 \mathrm{H}, \mathrm{d}, J 17.7,5-\mathrm{H})$, $4.62(1 \mathrm{H}, \mathrm{d}, J 17.7,5-\mathrm{H}), 6.83(1 \mathrm{H}, \mathrm{s}, 12 \mathrm{a}-\mathrm{H}), 7.21(1 \mathrm{H}, \mathrm{d}, J 8.3$, $11-\mathrm{H}), 7.30(1 \mathrm{H}, \mathrm{m}, 9-\mathrm{H}), 7.61(5 \mathrm{H}, \mathrm{m}, \operatorname{Ar}-\mathrm{H}), 7.70(1 \mathrm{H}, \mathrm{m}$, $10-\mathrm{H}), 7.96(1 \mathrm{H}$, dd, $J 8.1,1.3,8-\mathrm{H})$ (Found: C, 66.3; H, 4.1; $\mathrm{N}, 11.5 . \mathrm{C}_{20} \mathrm{H}_{15} \mathrm{~N}_{3} \mathrm{O}_{4}$ requires C, 66.5; H, 4.2; $\mathrm{N}, 11.6 \%$ ).
