# Crystal Structure of Bis-p-nitrophenylcarbodi-imide, $\mathrm{O}_{2} \mathrm{~N} \cdot \mathrm{C}_{6} \mathrm{H}_{4} \cdot \mathrm{~N}: \mathrm{C}: \mathrm{N} \cdot-$ $\mathrm{C}_{6} \mathrm{H}_{4} \cdot \mathrm{NO}_{2} \dagger$ 

By A. T. Vincent and P. J. Wheatley, ${ }^{*}$ Department of Physical Chemistry, Lensfield Road, Cambridge, CB2 1 EP

Crystals of the title compound (I) are orthorhombic with $a=24.738, b=3.827 . c=13.277 \AA . Z=4$. space group Pna $2_{1}$. The structure was solved by direct methods. 1205 Visually estimated $X$-ray intensities were refined by full-matrix least-squares to $R 7 \cdot 73 \%$. The molecule differs markedly from an idealised allene type. Important differences (idealised values in parentheses) are: $\mathrm{C}-\mathrm{N}=\mathrm{C} 129 \cdot 6$ and $134 \cdot 4^{\circ}\left(120^{\circ}\right) . \mathrm{N}=\mathrm{C}=\mathrm{N} 169 \cdot 7^{\circ}\left(180^{\circ}\right)$, and $\mathrm{C}-\mathrm{N} \cdots \mathrm{N}-\mathrm{C}$ torsion angle $113 \cdot 5^{\circ}\left(90^{\circ}\right)$.

The first accurate structure determination of a carbodiimide has recently been reported. ${ }^{1}$ There are no unexpected features and the molecule has the expected allene-type structure. This is in contrast to the vinylideneamines, containing the $\mathrm{C}: \mathrm{C}: \mathrm{N}$ group, which often show anomalous values for the angle at the nitrogen atom with variations from 123 to $180^{\circ} .^{2-5}$ Preliminary work on bis- $p$-nitrophenylcarbodi-imide, (I), $\mathrm{O}_{2} \mathrm{~N}^{-} \mathrm{C}_{6} \mathrm{H}_{4}^{-}$ $\mathrm{N}: \mathrm{C}: \mathrm{N} \cdot \mathrm{C}_{6} \mathrm{H}_{4} \cdot \mathrm{NO}_{2}$, revealed a short axis of length $3.827 \AA$ which suggested that the molecule was either planar or of a distorted allene type.

The presence of nitro-groups in the molecule gave rise to speculation about their interaction with the aromatic rings and the para-substituent, in this case the cumulene chain, as observed in some aromatic nitro-compounds. Trotter ${ }^{6}$ has reported that $\mathrm{C}-\mathrm{NO}_{2}$ bond lengths in aromatic compounds are ca. $1.48 \AA$, which suggests that there is little evidence for the contribution of quinoidal structures to the resonance hybrid molecule. More recent structure determination of $p$-nitrophenol ( $\mathbf{1} 442$ and $1.445 \AA$ in the two crystal forms) ${ }^{7,8} p$-nitroaniline ( $1 \cdot 460 \AA$ ), ${ }^{9}$ and $N N$-dimethyl- $p$-nitroaniline ( $1 \cdot 405 \AA$ ), ${ }^{10}$ have suggested that the inclusion of an electron-donating group in addition to the nitro-group results in the quinoidal structure playing a more important role. On the other hand, a recent neutron diffraction study of 1,3,5-trinitrobenzene (two independent molecules) ${ }^{11}$ revealed $\mathrm{C}-\mathrm{NO}_{2}$ bond lengths in the range 1.442 $1.500 \AA$ so that the criterion of $\mathrm{C}-\mathrm{NO}_{2}$ bond lengths (vide infra) is perhaps suspect. The $\mathrm{C}-\mathrm{NH}_{2}$ bond lengths in aromatic amino-compounds are significantly shorter than the $\mathrm{C}-\mathrm{NO}_{2}$ lengths in aromatic nitro-compounds, e.g. $p$-nitroaniline ( $1 \cdot 371 \AA$ ) and 2 -amino- 3 methylbenzoic acid ( $1.367 \AA$ ). ${ }^{12}$

## EXPERIMENTAL

Crystal Data.- $\mathrm{C}_{13} \mathrm{H}_{8} \mathrm{~N}_{4} \mathrm{O}_{4}, M=\mathbf{2 8 4} \cdot \mathbf{2}$. Orthorhombic, $a$ $=24.738(12), b=3.827(6), c=13.277(8) \AA, U=1257.0 \AA^{3}$, $D_{\mathrm{m}}=1 \cdot 48, Z=4, D_{\mathrm{c}}=1 \cdot 50, F(000)=584$. Space group

The preparation of suitable single crystals proved to be difficult as slow conversion into a substituted urea occurred during recrystallisation. Rigorous drying of all solvents proved necessary, and the compound was then reluctant to crystallise by any of the methods used. Eventually several thin plates were obtained by slow evaporation of a solution in 1:1 acetone-chloroform. Two crystals were found to be suitable for intensity measurements with dimensions $c a$. $0.06 \times 0.56 \times 0.48$ and $0.10 \times 0.26 \times 0.30 \mathrm{~mm}$.

Cell dimensions were obtained from oscillation and Weissenberg photographs. Intensities were collected from equi-inclination Weissenberg photographs of the $h k 0-12$ and $h 0-3 l$ layers and estimated visually. 1215 Independent reflexions were assigned non-zero intensity and were corrected for Lorentz and polarisation effects. Ten of the reflexions were considered to be suitable and necessary for the solution of the structure but not for refinement. Several reflxions had bad spot shape and were not estimated. Intensities were placed on the same scale through common reflexions.
Structure Determination and Refinement.-The structure was solved by direct methods using a modified version of the weighted tangent scheme of ref. 13. Table $1(a)$ gives an analysis of the $|E|$ distribution which clearly confirms a non-centrosymmetric space group. Table $1(b)$ gives the starting set of 10 planes and the assigned phases which led to 1024 possible combinations. Three phases were chosen to determine the origin (parity groups $u u g, g u u$, and $g u g$ ) and a fourth plane (parity group ggg) to select the enantiomorph. Six other planes were selected so that all parity groups had at least one plane in the starting set. From the 1024 possible combinations 10 were selected on the basis of the lowest reliability index, $R_{\text {K }}$, generated after one unit-weight cycle of tangent refinement. 10 Cycles of weighted tangent refinement ( $220|E|$ values $>1 \cdot 3$ ) were then applied to these ten best solutions and final values of $R_{\text {K }}$ calculated in each case. The $R_{\text {K }}$ values ranged from 22.7 to $35.0 \%$ with the lowest value not having reached convergence. An $E$-map calculated with the phases corresponding to the lowest value of $R_{\mathrm{K}}$ revealed positions for all non-hydrogen atoms. Two cycles of full-matrix leastsquares refinement ( 318 planes) with a single isotropic temperature factor reduced $R$ from 22.6 to $\mathbf{1 2 . 7} \%$. Refinement with the full data set ( 1205 planes) and with individual

(b) Starting phases used to generate the 1024 possible combinations from which 10 phase sets were chosen for weighted tangent refinement *

* These phases yielded a set of atomic co-ordinates which were then inverted to give the co-ordinates in Table 2. This inversion was done so that the hand of the present molecule would be consistent with the $p$-tolyl compound. ${ }^{1}$ All subsequent calculations have been performed with the co-ordinates given in Table 2.
isotropic thermal factors for carbon, nitrogen, and oxygen reduced $R$ to $12 \cdot 6 \%$. Further refinement was carried out with anisotropic temperature factors and the secondary extinction coefficient as a refinable parameter. ${ }^{15}$ At $R$ $8.4 \%$ phenyl group hydrogen atoms were introduced at calculated positions, new positions being obtained before each subsequent refinement cycle. Further anisotropic refinement of the non-hydrogen atoms with a single thermal factor for each group of phenyl hydrogen atoms produced a final $R$ value of $7.73 \%$. The ratio of the final mean shift to $\sigma$ was 0.007 for all parameters.

The weighting scheme was $w=1 /\left(2.51+F_{0}+0.017\right.$ $F_{0}{ }^{2}$ ) with the constants chosen from an analysis of the variance. ${ }^{16}$ Form factors ${ }^{17}$ were used in which the imaginary part was set equal to zero. Friedel's law was assumed in the data reduction, and no attempt was made to determine the absolute configuration.

Figure 1 Projection of the asymmetric unit down $a$ with the labelling of the atoms

## RESULTS

The labelling of the atoms is shown in Figure 1 and follows the same scheme as for di-p-tolylcarbodi-imide (II). ${ }^{1}$

Table 3. A similar analysis in terms of parity groups shows that the agreement is less good for groups ggg and $\operatorname{ggu} u$ ( $R 9.65$ and $8 \cdot 46 \%$ ) than for other groups ( $6.50-7 \cdot 40 \%$ ). This arises from the inclusion of a large number of $h 0 l$ reflexions collected about $c$ which had bad shape on all layers. $R$ for $203 \mathrm{~h} 0 l$ reflexions is $10.21 \%$. This feature probably accounts for $R$ not showing the normal significant decrease as a function of $F_{0}$. Many of the $h 0 l$ reflexions were strong and on average their intensity was higher than the $h k l$ reflexions. A Table of observed and calculated structure factors is published in Supplementary Publication No. SUP 20453 ( 13 pp., 1 microfiche).*

Bond lengths and angles are listed in Table 4. The mean $\mathrm{C}-\mathrm{C}$ length in the phenyl groups ( $1 \cdot 379 \AA$ ) is less than the standard value ( $1.394 \AA$ ). ${ }^{18}$ This compares with $1.386 \AA$ for di- $p$-tolylcarbodi-imide. The difference between $\mathrm{C}(1)-\mathrm{N}(1)$ and $\mathrm{C}(1)-\mathrm{N}(2)$ is not significant ( $<2 \sigma$ ). The $\mathrm{N}(1)-\mathrm{C}(11)$ and $\mathrm{N}(2)-\mathrm{C}(21)$ lengths ( 1.392 and $1 \cdot 406 \AA$ ) are very significantly less than the single-bond value ( $1 \cdot 475 \AA$ ) and, moreover, are significantly less than the equivalent bonds in the tolyl compound ( $1 \cdot 428$ and $1 \cdot 432 \AA$ ). The $\mathrm{C}-\mathrm{NO}_{2}$ lengths ( 1.459 and $1.453 \AA$ ) are similar to the lengths found in $p$-nitroaniline $(1 \cdot 460 \AA$, corrected for thermal motion) and $p$-nitrophenyl azide ( $1 \cdot 447 \AA$ ). ${ }^{9,19}$

The angle at the central carbon atom $\left(169 \cdot 7^{\circ}\right)$ is similar to that found in other cumulenes ${ }^{1-5}$ and probably deviates from $180^{\circ}$ as a result of packing forces. The $\mathrm{C}-\mathrm{C}-\mathrm{C}$ angles at the nitro-groups ( 121.5 and $122 \cdot 6^{\circ}$ ) are the largest in each phenyl group, a common feature of aromatic nitro-compounds. ${ }^{7-11,19}$ In comparison, the tolyl compound has its largest ring angles at non-substituted carbon atoms. The

[^0]larger angles assumed by $\mathrm{N}(1)-\mathrm{C}(11)-\mathrm{C}(12)$ and $\mathrm{N}(2)-\mathrm{C}(21)--$ $\mathrm{C}(26)$ (121.4 and $123 \cdot 3^{\circ}$ ) than by $\mathrm{N}(1)-\mathrm{C}(11)-\mathrm{C}(16)$ and $\mathrm{N}(2)-\mathrm{C}(21)-\mathrm{C}(22)\left(117.9\right.$ and $\left.116.5^{\circ}\right)$ are probably due to the intramolecular contacts of $C(12)$ and $C(26)$ with the cumulene chain. $C(16)$ and $C(22)$ do not have similar contacts. The $\mathrm{C}-\mathrm{N}=\mathrm{C}$ angles ( $134 \cdot 4$ and $129 \cdot 6^{\circ}$ ) are slightly larger than in the tolyl compound ( 127.2 and $128.4^{\circ}$ ), both pairs being significantly larger than the idealised allene type value $\left(120^{\circ}\right)$.

Table 5 gives equations for some least-squares planes and deviations of atoms from these planes. The deviations for planes (1)-(4) are very similar to those found in the tolyl compound. The $\mathrm{NO}_{2}$ group containing $\mathrm{N}(3)$ and the $\mathrm{C}=\mathrm{N}-\mathrm{C}$ chain containing $\mathrm{N}(2)$ are much more nearly in the plane of the phenyl group to which they are attached than is the case for the corresponding groups of atoms in the other half of the molecule. This feature is emphasised by the torsion angles given in Table 6 but it does not seem to manifest itself in any large differences in bond lengths in the two halves of the molecule. The torsion angle $\mathrm{C}(11)-\mathrm{N}(1)$ $\cdots \mathrm{N}(2)-\mathrm{C}(21)$ is $113.5^{\circ}$ which is a considerable deviation from that in an idealised allene-type structure $\left(90^{\circ}\right)$. The tolyl compound does not exhibit this feature.

Figure 2 shows the packing of the molecules in the crystal. Due to the short $b$ axis, every atom is separated from two identical atoms in this direction by the length of $b(3.827 \AA)$.

$$

Several of the shortest contacts shown in Table 7 are due to this purely translational symmetry. No contacts are, however, unduly short. The packing arrangement in the tolyl compound is different in that the closest contacts are between molecules related by two-fold screw axes. The shortest contacts involving oxygen atoms with non-hydrogen atoms involve the oxygen atoms bonded to $\mathrm{N}(4)$ (3.09$3 \cdot 25 \AA$ ). The shortest contacts experienced by the oxygen

Table 6
Torsion angles $\left({ }^{\circ}\right)$

| $\mathrm{C}(11)-\mathrm{N}(1) \cdots \mathrm{N}(2)-\mathrm{C}(21)$ | $113 \cdot 5$ |
| :--- | ---: |
| $\mathrm{C}(1)-\mathrm{N}(1)-\mathrm{C}(11)-\mathrm{C}(12)$ | $31 \cdot 6$ |
| $\mathrm{C}(1)-\mathrm{N}(1)-\mathrm{C}(11)-\mathrm{C}(16)$ | $27 \cdot 6$ |
| $\mathrm{C}(1)-\mathrm{N}(2)-\mathrm{C}(21)-\mathrm{C}(22)$ | $6 \cdot 5$ |
| $\mathrm{C}(1)-\mathrm{N}(2)-\mathrm{C}(21)-\mathrm{C}(26)$ | $5 \cdot 3$ |

atoms on $\mathrm{N}(3)$ are substantially longer $[\mathrm{O}(32) \cdots \mathrm{O}(42)$ $3 \cdot 77, \mathrm{O}(31) \cdots \mathrm{N}(1) \quad 3 \cdot 44$, and $\mathrm{O}(31) \cdots \mathrm{C}(16) 3 \cdot 40 \AA]$. This feature can be correlated with the lower thermal factors of $O(41)$ and $O(42)$ compared with $O(31)$ and $O(32)$. The $3.09 \AA$ contact of $\mathrm{O}(41)$ is with the central carbon atom $\mathrm{C}(1)$ : the shortest contact with a carbon atom that is bonded to a hydrogen atom is $3 \cdot 20 \AA$. The oxygen atoms are involved in a large number of relatively short intermolecular contacts, but none is short enough to suggest the presence of hydrogen bonding.

Table 7

## discussion

The primary objective of this analysis was to determine the relationship between the short $b$ axis and the stereochemistry of the molecule. The main structural features is the adoption of a distorted allene-type configuration which allows the molecule to pack with $3.827 \AA$ translational symmetry.

Table 8 compares structural features with equivalent ones in di- $p$-tolylcarbodi-imide (II) and in $N$ - $p$-tolyl-2,2-diphenylvinylideneamine (III), $\mathrm{Ph}_{2} \mathrm{C}: \mathrm{C}: \mathrm{N} \cdot \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}$. The bond lengths and angles in (II) and (III) are very similar for the half of the molecule which comes closest to being planar $[\mathrm{C}(1), \mathrm{N}(2), \mathrm{C}(21)-(26)]$. The introduction of a nitro-group appears to have two important effects. The first involves the torsion angle, as discussed earlier. The second is the significant reduction (ca. $4 \sigma$ ) in the $\mathrm{C}(11)-\mathrm{N}(1)$ and $\mathrm{C}(21)-\mathrm{N}(2)$ bond lengths. The shortening of these bonds could be due to a signi-
ficant contribution of a quinoidal structure to the hybrid molecule, the lone pairs on the nitrogen being the source of electron donation. A consequence of this would be a change in the $\mathrm{N}=\mathrm{C}=\mathrm{N}$ bonding which can be detected in the deviation from an allene-type structure. However, confirmatory evidence from the $\mathrm{C}-\mathrm{C}$ bond lengths in the phenyl groups is not so strong, as only one of the aromatic rings [ $\mathrm{C}(21)-(26)]$ shows a shortening in the 2,3- and 5,6-bonds. Evidence from the $\mathrm{C}-\mathrm{NO}_{2}$ bond lengths is inconclusive in this respect.

The correlation between $\mathrm{N}=\mathrm{C}$ lengths and the value of the angle at the nitrogen atom remains consistent with previous results. ${ }^{1-5}$
