# Crystal and Molecular Structure of Sceletium Alkaloid $A_{4}$ by X-Ray Analysis 

By P. A. Luhan and A. T. McPhail,* Paul M. Gross Chemical Laboratory, Duke University, Durham, North Carolina 27706, U.S.A.

Sceletium Alkaloid A. (1). $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{~N}_{2} \mathrm{O}_{2}$, isolated from Sceletium namaquense $L$. Bolus crystallizes in the monoclinic system. space group $P 2_{1}$. with $a=8 \cdot 33(2) . b=14 \cdot 74(3) . c=7 \cdot 18(2) A . \beta=95 \cdot 04(20)^{\circ}$. and $Z=2$. The structure was solved from photographic $X$-ray data by direct phase-determining methods and refined by full-matrix least-squares calculations to $R \quad 0 \cdot 100$ over 1523 observed reflexions. The alkaloid which contains a 2,3disubstituted pyridine moiety is representative of a third structure variant in Sceletium species.

During the course of their studies on the alkaloid constituents of Sceletium species (family Aizoaceae) Jeffs ${ }^{1}$ and his co-workers isolated from Sceletium namaquense a minor alkaloid of composition $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{~N}_{2} \mathrm{O}_{2}$. Comparison of the properties of this alkaloid with those of ' Sceletium $\mathrm{A}_{4}$ ', an alkaloid of unknown constitution reported by Popelak and Lettenbauer, ${ }^{2}$ proved them to

be identical. Mass spectral, n.m.r., i.r., and u.v. data indicated that the alkaloid was a representative of a new structural type of sceletium alkaloid containing a 2,3-disubstituted pyridine ring, and the number of probable structures for the alkaloid could be reduced to four of which (1) seemed the most probable on biogenetic grounds. ${ }^{3}$ Since only a small amount of alkaloid was available we undertook a single-crystal $X$-ray analysis

to the isolation and characterization of the same alkaloid from Sceletium tortuosum N.E.Br.

## EXPERIMENTAL

Crystals \{m.p. $\left.153.5-154.5^{\circ} \mathrm{C},[\alpha]_{\mathrm{D}}(\mathrm{MeOH})+131^{\circ}\right\}$ were obtained from ethyl acetate as prisms.
Crystal Data.- $\mathrm{C}_{20} \mathrm{H}_{24} \mathrm{~N}_{2} \mathrm{O}_{2}, M=324 \cdot 4$. Monoclinic, $a=$ $8.33(2), b=14.74(3), c=7.18(2) \AA, \beta=95.04(20)^{\circ}, U=$ $878 \AA^{3}, \quad D_{\mathrm{m}}=1 \cdot 23, \quad Z=2, \quad D_{\mathrm{c}}=1 \cdot 227, \quad F(000)=348$. $\mathrm{Cu}-K_{\alpha} X$-rays, $\lambda=1.542 \AA ; \mu\left(\mathrm{Cu}-K_{\alpha}\right)=6.4 \mathrm{~cm}^{-1}$. Space group $P \mathbf{1}_{1}\left(C_{2}^{2}\right)$ from systematic absences: $0 k 0$ when $k \neq 2 n$; Sceletium Alkaloid $\mathrm{A}_{4}$ is a chiral molecule.

Crystallographic Measurements.-Oscillation, rotation, and Weissenberg photographs were taken with $\mathrm{Cu}-K_{\alpha}$ radiation; precession photographs were recorded with Mo- $K_{\alpha}(\lambda=0.7107 \AA)$ radiation. The unit-cell dimensions were evaluated from precession, rotation, and $h 0 l$ Weissenberg photographs. Intensities were estimated visually from equi-inclination multiple-film Weissenberg photographs of the $h 0-13 l$ layers by comparison with a calibrated intensity strip. Spot-shape corrections and the usual Lorentz and polarization factors were applied, but absorption was neglected. In all, 1523 independent nonzero structure amplitudes were derived.

Structure Analysis.-Normalized structure factor magnitudes $\left|E_{H}\right|$ were computed from the relationship $\left|E_{H}\right|^{2}=$ $\left|F_{H}\right|^{2} / \varepsilon \sum_{j=1}^{N} f^{2}{ }_{j}{ }_{H}$ where $N$ is the number of atoms in the unit cell, $f_{j_{H}}$ is the atomic scattering factor of the $j^{\text {th }}$ atom. For the space group $P 2_{1}, \varepsilon=1$ except for $0 k 0$ reflexions where $\varepsilon=2$. The $\left|F_{H}\right|^{2}$ values were those from which the effects of thermal motion were removed by assuming an overall isotropic temperature factor $B=3 \cdot 5 \AA^{2}$.

The initial phases for a selected set of reflexions with

5 J . Karle and I. L. Karle, Acta Cryst., 1966, 21, 849.
${ }^{6}$ J. Karle and H. Hauptmann, Acta Cryst., 1956, 9, 635.
large $|E|$ values were determined by the symbolic addition procedure ${ }^{5}$ for non-centrosymmetric crystals. The formula for starting the phase determination was $\phi_{H} \simeq<\phi_{K}+$ $\phi_{H-K}>K_{r}$ where $\phi_{H}$ were the phase associated with $\left|E_{H}\right|$ and the average was taken over those $K$ corresponding to the larger $|E|$ values. Phases, $\phi_{H}$, were assigned to three linearly independent reflexions (207, $|E|=3.63, \phi=0$; $294,|E|=2 \cdot 37, \phi=\pi / 2 ; 58 \overline{2},|E|=2 \cdot 28, \phi=0$ ) in order to specify the origin of the space group $P 2_{1}$. Two other reflexions (485, $|E|=2 \cdot 61$, and $544,|E|=2.61$ ) which entered into a number of $\Sigma_{2}$ combinations were assigned symbols $a$ and $b$, and a set of phases for 22 reflexions for which $E_{H} \cdot E_{K} \cdot E_{H-K}>10 \cdot 0$ were derived in terms of the five starting phase angles. The values of $a(0 \leqslant a \leqslant \pi)$ and $b(0 \leqslant b \leqslant 2 \pi)$ were then allowed to vary by increments of $\pi / 4$ and these were input to the tangent formula: ${ }^{6}$

$$
\begin{aligned}
& \tan \phi_{H} \simeq\left[\Sigma_{K}\left|E_{K} \cdot E_{H-K}\right| \cdot \sin \left(\phi_{K}+\phi_{H-K}\right)\right] / \\
& \quad\left[\Sigma_{K}\left|E_{K} \cdot E_{H-K}\right| \cdot \cos \left(\phi_{K}+\phi_{H-K}\right)\right] \simeq A / B
\end{aligned}
$$

the restriction on $a$ being equivalent to specifying the enantiomorph. For these calculations we employed a local version of the iterative program originally written by Drew ${ }^{7}$ and amended by Larson and Motherwell. ${ }^{8}$ The largest $58|E|$ values were included with the original 22 in the iterations for the first 5 cycles, 250 were refined during the next 5 cycles, and 498 were refined for the final 5 cycles. A phase assignment was rejected in any cycle if the consistency index, $t=\sqrt{A^{2}+B^{2}} / \Sigma_{K}\left|E_{K}\right| \cdot\left|E_{H-K}\right|$ was $<0 \cdot 40$, and the value of $\alpha=\left|E_{H}\right| \sqrt{A^{2}+B^{2}}$ was $<6.0$ At the end of the tangent refinement cycles, inspection of the $R_{K}[=$ $\left.\left.\Sigma_{H}| | E_{H}\right|_{\text {obs }}-\left.\left|E_{H}\right|_{\text {calc }}\left|/ \Sigma_{H}\right| E_{H}\right|_{\text {obs }}\right]$ values revealed that one of the lowest ( $R_{K}=16.0$ ) was for the starting set $a=$ $3 \pi / 4, b=\pi$, which also used a large number of the $\Sigma_{2}$ values and assigned phases to a larger number of reflexions than the other sets. An E-map was computed using the phase values derived from this set, and a seven-atom [ $\mathrm{C}\left(\mathbf{1}^{\prime}\right)-\left(6^{\prime}\right)$, $C(3 a)]$ partial structure was recognized. These atoms were then used to calculate structure factors. 84 Reflexions with $|E|>1.0$ and for which, summing over those atoms not included in the structure-factors calculation, $\tanh \left(F_{0} \cdot F_{\mathrm{c}} /\right.$ $\Sigma_{f_{j}}{ }^{2}$ ) exceeded $0 \cdot 60$, were used as input to the tangent formula which generated phases for 385 reflexions with $|E|>1 \cdot 0$. A second $E$-map was computed and a further eight atoms were located to give partial structure (4). Positional and isotropic thermal parameters of these fifteen atoms were refined by four cycles of full-matrix leastsquares calculations to $R 0.37$. A three-dimensional $F_{0}$ Fourier synthesis was then evaluated, and the positions of the remaining non-hydrogen atoms were revealed clearly in the electron-density distribution. Atomic positional and anisotropic thermal parameters were refined by seven cycles of least-squares calculations which reduced $R$ to 0.130 . During these and all subsequent calculations the $y$ coordinate of $\mathrm{N}(1)$ was held constant to define the origin of the space group. The pyridine nitrogen atom was identified during the calculations from its relatively low thermal parameter when treated as a carbon atom and from the values of the diagonal elements of the normal-equation matrix. A three-dimensional difference electron density map was evaluated, and this contained significant density
${ }^{7}$ See e.g., M. G. B. Drew, D. H. Templeton, and A. Zalkin, Acta Cryst., 1969, B, 25, 261 .
${ }^{8}$ See e.g., O. Kennard, D. L. Wampler, J. C. Coppola, W. D. S. Motherwell, D. G. Watson, and A. C. Larson, Acta Cryst., 1971, $B, 27,1116$.
at all positions calculated for the hydrogen atoms (assuming $\mathrm{C}-\mathrm{H} \quad 1.07 \AA$ ). Inclusion of twenty-four hydrogen atoms with $B=5 \cdot 0 \AA^{2}$ in the next structure-factor calculation reduced $R$ to $0 \cdot 113$. Four further least-squares iterations to adjust the non-hydrogen atom parameters brought the refinement to convergence with $R 0 \cdot 100$. For all structurefactor calculations, scattering factors for neutral atoms were taken from ref. 9. The weighting scheme used in the leastsquares calculations was $\sqrt{ } w=1$ for $\left|F_{0}\right| \leqslant 6.0$ and $\sqrt{ } w$ $=\left|F_{0}\right| / 6.0$ for $\left|F_{0}\right|>6.0$; this showed no systematic dependence of $\left\langle w \Delta^{2}\right\rangle$ when analysed in ranges of $\left|F_{0}\right|$ and $\sin \theta . \dagger$

## RESULTS AND DISCUSSION

This $X$-ray analysis establishes the structure of Sceletium Alkaloid $\mathrm{A}_{4}$ as (1) or its mirror image. We assume that (l) also represents the absolute stereochemistry in accord with those assigned previously to ( - )-mesembrine ${ }^{10}$ (3) and to 6 -epimesembranol methiodide ${ }^{11}$ (4). Final atomic positional and thermal parameters are given in Tables 1-3, and the interatomic

distances and valency angles are in Table 4. Figure 1 shows the conformation adopted by the molecule in the crystal. Torsion angles ${ }^{12}$ for rings $A$ and $B$ are shown in Figure 2, and the displacements of some atoms from selected mean planes through groups of atoms are presented in Table 5.

The atoms of the pyridine ring are coplanar within the accuracy of the analysis, but the substituent atoms, $C(5)$ and $C(7 a)$, are displaced significantly by 0.041 and $0 \cdot 105 \AA$, respectively, to the same side of the ring plane. Ring в adopts a half-chair conformation with C(3a) and $\mathrm{C}(4)$ displaced by 0.406 and $-0.387 \AA$ from the mean

The superscripts refer to the following co-ordinate transformations:

$$
\mathrm{I}-x, \frac{1}{2}+y, \mathrm{I}-z \quad \text { II } \mathrm{I}-x, \frac{1}{2}+y, \mathrm{I}-z
$$

Table 5
Displacements ( $\AA$ ) of the atoms from various planes. Atoms not included in the derivation of the plane are italicized
Plane A: $\mathrm{C}(2) 0 \cdot 0, \mathrm{C}(3) 0 \cdot 0, \mathrm{C}(3 \mathrm{a}) 0 \cdot 0, N(1)-0 \cdot 362, C(7 a)$ 0.351

Plane $\mathrm{B}: ~ C(5)-0.005, \mathrm{C}(6) 0.011, \mathrm{C}(7)-0.011, \mathrm{C}(7 \mathrm{a}) 0.005$, $C(3 a) 0.406, C(4)-0.387$
Plane $c: ~ C(6)-0.004, C(7)-0.001, N(9)-0.003, C(10) 0.014$, $\mathrm{C}(11)-0.019, \mathrm{C}(12) 0.012, C(5) 0.041, C(7 a) 0.105$
Plane D: C(1) 0.012, C( $\left.2^{\prime}\right) \quad 0.019, ~ C\left(3^{\prime}\right) \quad 0.004, ~ C\left(4^{\prime}\right) \quad 0.001$, $\mathrm{C}\left(5^{\prime}\right)-0.003, \mathrm{C}\left(6^{\prime}\right)-0.025, \mathrm{O}(\mathrm{I} 3)-0.027, \mathrm{O}(15)$ $0.018, C(14)-0.142, C(16) 0.110, C(3 a)-0.139$, $C(3) 0.980$
consequently there is an increased degree of rotational freedom about the $\mathrm{C}(3 \mathrm{a})-\mathrm{C}\left(6^{\prime}\right)$ bond in order to reduce non-bonded $\mathrm{H} \cdot \mathrm{H}$ interactions, although free rotation is still restricted by such interactions. The $\mathrm{H}\left(5^{\prime}\right) \cdots$ $\mathrm{H}(7 \mathrm{a})$ distance in (1) is $2.17 \AA$ whereas the corresponding estimated separation in (4) is $1 \cdot 76 \AA$. A consequence of the reduced non-bonded interaction in (1) is that the exocyclic angles at $C\left(6^{\prime}\right)$ are equal in contrast to the large observed difference ( $116 \cdot 8,125 \cdot 2^{\circ}$ ) in (4). The dihedral angle between the plane through $\mathrm{C}(7 \mathrm{a}), \mathrm{C}(3 \mathrm{a})$, and $C\left(6^{\prime}\right)$, and the phenyl ring plane is $10^{\circ}$.

The phenyl ring atoms and the substituent oxygen atoms are approximately coplanar (plane D ), but $\mathrm{C}(3 \mathrm{a})$

Figure 1 Atomic arrangement

Figure 2 Torsion angles in A and B rings of (1)
is significantly displaced $(0 \cdot 118 \AA)$ from the mean plane calculated through $\mathrm{C}\left(1^{\prime}\right)-\left(6^{\prime}\right), \mathrm{O}(13)$, and $\mathrm{O}(15)$. This displacement may be ascribed to the bending back of the phenyl ring at the $\mathrm{C}(3 \mathrm{a})-\mathrm{C}\left(6^{\prime}\right)$ bond in order to reduce non-bonded intramolecular interactions between the phenyl ring, and $\mathrm{H}(3)$, and $\mathrm{H}(7 \mathrm{a})$. In accord with our earlier observation ${ }^{11}$ on the geometries of adjacently bonded methoxy-groups in dimethoxyphenyl moieties, the $\mathrm{C}(\mathrm{Ph}) \cdots \mathrm{O}$ vectors are bent toward each other in (l) to reduce the intramolecular non-bonded $\mathrm{H}(\mathrm{Me}) \cdots$ $\mathrm{H}(\mathrm{Ph})$ interactions. The methyl groups are rotated co-operatively by small amounts about their $\mathrm{C}(\mathrm{Ph})-\mathrm{O}$ bonds so that $C(14)$ and $C(16)$ are displaced 0.142 and $0 \cdot 110 \AA$ to opposite sides of plane D (Table 5). The torsion angles about the $\mathrm{C}\left(3^{\prime}\right)-\mathrm{O}(13)$ and $\mathrm{C}\left(4^{\prime}\right)-\mathrm{O}(15)$ bonds are -5.4 and $-7.8^{\circ}$. Similar rotations are present ${ }^{11}$ in (4).

The mean $\mathrm{C}\left(s p^{3}\right)-\mathrm{C}\left(s p^{3}\right)$ bond length ( $1.549 \AA$ ) is close to the accepted value ${ }^{13}[1 \cdot 537(5) \AA]$. The $\mathrm{C}(\mathrm{Ph})-\mathrm{C}\left(s p^{3}\right)$ single-bond distance $\left[\mathrm{C}(3 \mathrm{a})-\mathrm{C}\left(6^{\prime}\right) \quad 1.534 \AA\right.$ ] is probably significantly longer $(\Delta / \sigma \simeq 3)$ than the accepted value ${ }^{13}$ $[1.505(5) \AA]$ for such bonds, the increase being due to

Figure 3 The crystal structure, as viewed in projection down $c^{*}$
steric overcrowding in this region of the molecule. The $\mathrm{C}\left(s p^{2}\right)-\mathrm{C}\left(s p^{3}\right)$ bonds from the pyridine ring average $1.514 \AA$. The mean $\mathrm{C}(\mathrm{Ph})-\mathrm{O}$ and $\mathrm{C}(\mathrm{Me})-\mathrm{O}$ lengths ( 1.362 and $1.411 \AA$ ) agree satisfactorily with the corresponding mean distances ( 1.359 and $1.440 \AA$ ) in re-
${ }_{13}$ Chem. Soc. Special Publ., No. 11, 1958, No. 18, 1964.

${ }^{15}$ S. R. Hall and F. R. Ahmed, Acta Cryst., 1968, B, 24, 346.
serpine ${ }^{14}$ and cryptopine ( 1.371 and $1.426 \AA$ )..$^{15}$ In the phenyl ring, the mean $\mathrm{C}-\mathrm{C}$ length ( $1 \cdot 391 \AA$ ) is in good agreement with the accepted value ${ }^{13}[1 \cdot 394(5) \AA]$. There is, however, an alternation of bond lengths in the phenyl ring and the methyl groups of the methoxysubstituents are cis to two of the shorter bonds. Similar cis orientations of methyl groups to short bonds have been noted elsewhere for other molecules. ${ }^{16}$ In the pyridine ring, the mean $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{N}$ distances are 1.385 and $1.345 \AA, \mathrm{C}-\mathrm{N}-\mathrm{C}$ is $117 \cdot 0^{\circ}$, and the mean angles at the $\alpha$-carbon atoms are $123.5^{\circ}$. These dimensions are in excellent agreement with those reported for pyridine ${ }^{17}$ $\left[\mathrm{C}-\mathrm{C} 1.395(5)\right.$ and $\mathrm{C}-\mathrm{N} 1 \cdot 340(5) \AA ; \mathrm{C}-\mathrm{N}-\mathrm{C} 116.7^{\circ}$ and $\mathrm{C}-\mathrm{C}-\mathrm{C}=124 \cdot 0^{\circ}$ at the $\alpha$-carbon atoms]. The mean $\mathrm{C}\left(s p^{3}\right)-\mathrm{N}$ distance $(1.456 \AA)$ is satisfactorily close to the standard value ${ }^{13}$ [ $1 \cdot 472(5) \AA$ ].

The molecular packing in the crystal, viewed down the $c^{*}$ axis is shown in Figure 3. There are no abnormally short intermolecular distances.

We thank Dr. P. W. Jeffs for the crystals and for discussions, and Dr. D. G. Watson for providing a listing of the tangent-refinement programme. Calculations were performed on the IBM 360/75 computer at the Triangle Universities Computation Center, Research Triangle Park, North Carolina, and supported in part by the U.S. National Science Foundation. Partial financial support through a Biomedical Sciences Support Grant from the U.S. National Institutes of Health to Duke University is acknowledged.
