# Crystal and Molecular Structure of cis-1,1-Bismethoxycarbonyl-4amethyldecahydronaphthalene 

By A. T. McPhail * and Pui-Suen Wong, Paul M. Gross Chemical Laboratory, Duke University, Durham, North Carolina 27706, U.S.A.<br>D. M. S. Wheeler, Department of Chemistry, University of Nebraska, Lincoln, Nebraska 68508, U.S.A.

Single-crystal $X$-ray analysis of the title compound has established its molecular dimensions and preferred conformation. Crystals are monoclinic, space group $P 2_{1} / c, a=11 \cdot 52(2), b=7 \cdot 68(1), c=20 \cdot 10(3) A, \beta=125 \cdot 58(20)^{\circ}$, $Z=4$. The structure was solved by direct phase-determining methods and refined by full-matrix least-squares calculations to $R 0 \cdot 103$ over 2156 independent reflections. The presence of 1,3-diaxial interactions leads to significant deviations in bond lengths and valency angles from their normal values. The $\mathrm{C}=0$ ester groups are approximately in a syn-planar orientation with respect to the $C(\alpha)-C(\beta)$ bonds.

Kröniger and Wheeler ${ }^{1}$ reported recently that the reaction of a mixture of the epimeric dimesylates, (1a) and (lb), with malonic ester in the presence of base gave the compound (2a). The structure and stereochemistry [including the conformation (2a) as opposed to (2b)] was suggested on the basis of mechanistic considerations and spectroscopic (particularly n.m.r.) data. However the monocarboxylic acid (3) obtained from (2a) had m.p. close to that of a known 9 -methyldecalincarboxylic acid for which a trans-ring-junction had been suggested. ${ }^{2}$

(3)

None of this latter material was available as a sample. We therefore examined compound (2a) by $X$-ray crystallography to determine definitely its structure and stereochemistry.

## EXPERIMENTAL

Crystal Data.- $\mathrm{C}_{15} \mathrm{H}_{24} \mathrm{O}_{4}$, m.p. $91^{\circ}, M=268 \cdot 4$. Monoclinic, $\quad a=11 \cdot 52(2), \quad b=7 \cdot 68(1), \quad c=20 \cdot 10(3) \AA, \quad \beta=$ $125 \cdot 58(20)^{\circ}, U=1440 \AA^{3}, D_{\mathrm{m}}=1 \cdot 23, Z=4, D_{\mathrm{c}}=1 \cdot 238$,

[^0]$F(000)=584$. Space group $P 2_{1} / c\left(C_{2 h}^{5}\right)$ from systematic absences: $0 k 0$ when $k \neq 2 n$, and $h 0 l$ when $l \neq 2 n$. $\mathrm{Cu}-K_{\alpha}$ radiation, $\lambda=1.542 \AA ; \mu\left(\mathrm{Cu}-K_{\alpha}\right)=7.3 \mathrm{~cm}^{-1}$.

Crystallographic Measurements.-Unit-cell dimensions were obtained from precession photographs taken with Mo- $K_{\alpha}(\lambda=0.7107 \AA)$ radiation, and an $h 0 l$ Weissenberg photograph taken with $\mathrm{Cu}-K_{\alpha}$ radiation. Intensity data for the $h 0-7 l$ layers were recorded photographically by the equi-inclination multiple-film Weissenberg method and estimated visually by comparison with a calibrated intensity strip. After the usual Lorentz, polarization, and spot-shape corrections were applied, 2156 independent structure amplitudes were obtained.

Structure Determination.-The data were placed on an approximately absolute scale and normalized structure factor magnitudes $\left|E_{H}\right|$ derived. The structure was solved by use of direct phase-determining methods employing the symbolic addition procedure ${ }^{3}$ and tangent formula ${ }^{4}$ refinement. Three origin-defining reflections $4,7,4,|E|=2 \cdot 79$; $8,6, \overline{11},|E|=2.93 ; 3,7,2,|E|=2 \cdot 60$, were assigned phases of zero, and three other reflections $6,1, \overline{16},|E|=2.51$; $0,0,14,|E|=2 \cdot 76 ; 2,7, \overline{13},|E|=2 \cdot 66$, were assigned symbolic phases. The most probable values for the symbolic phases were obtained through application of a local version of the iterative programme originally written by Drew ${ }^{5}$ and modified by Larson and Motherwell. ${ }^{6}$ A three-dimensional $E$-map was computed using the phases thus derived for 344 reflections with $|E|>1 \cdot 0$, and this distribution revealed clearly positions for all the nonhydrogen atoms.

Atomic positional and isotropic thermal parameters were then refined for four cycles of full-matrix least-squares calculations which minimized $\Sigma w\left(F_{o}-F_{\mathrm{c}}\right)^{2}$. At the end of this procedure the individual scale factors were adjusted to ensure $\Sigma k\left|F_{\mathrm{o}}\right|=\Sigma\left|F_{\mathrm{c}}\right|$, and $R$ was reduced from its initial value of 0.34 for the model derived from the $E$-map to $0 \cdot 18$. Subsequently, the carbon and oxygen atoms were allowed to assume anisotropic thermal parameters. Two cycles decreased $R$ to $0 \cdot 13$. Approximate positions for the ring hydrogen atoms were calculated by assuming $\mathrm{C}-\mathrm{H} 1.07 \AA$ and tetrahedral angles at the carbon atoms. For the methyl groups the model employed was, at $\mathrm{C}(9)$ a staggered $\mathrm{C}-\mathrm{H}$ arrangement with respect to the $C(4 a)-C$ bonds was assumed; in the ester groups one hydrogen atom was taken to be in the plane of the ester group and trans to the $\mathrm{C}=\mathrm{O}$

[^1]bond while the other two were assumed to be equally displaced above and below the ester group plane. A threedimensional difference electron-density map was then computed and this revealed significant positive density at all positions calculated for the hydrogen atoms. Inclusion of the hydrogen atoms in the next round of structure-factor calculations reduced $R$ to $0 \cdot 112$. Two further cycles of least-squares adjustment of the carbon and oxygen parameters brought the refinement to convergence at $R 0 \cdot 103$.

For all structure-factor calculations, scattering factors for neutral atoms were taken from ref. 7. In the least-squares iterations, the weighting scheme used was $\sqrt{ } w=1$ for
placements of selected atoms from some least-squares planes are in Table 3.

The $X$-ray analysis confirms the structure deduced from spectroscopic evidence. ${ }^{1}$ The molecule adopts conformation (2a) with both cyclohexane rings in chair conformations, and the methyl substituent and one of the methoxycarbonyl groups are axially oriented on the same ring. The alternative conformation ( 2 b ) would involve more severe, unfavourable 1,3-diaxial interactions between the methoxycarbonyl and hydrogen atoms on $C(5)$ and $C(7)$. By contrast, n.m.r. data ${ }^{1}$ suggest that

* These are the values of $b_{i j}$ in the expression $\exp \left(-B \sin ^{2} \theta / \lambda^{2}\right)=\exp -\left[\left(b_{11} h^{2}+b_{22} k^{2}+b_{33} l^{2}+b_{12} h k+b_{13} h l+b_{23} h l\right)\right]$.
$\dagger$ For all the hydrogen atoms an isotropic temperature factor, $B 3.5 \AA^{2}$, was used.
$\left|F_{\mathrm{o}}\right| \leqslant 9 \cdot 0$, and $\sqrt{ } w=\left|F_{\mathrm{o}}\right| / 9 \cdot 0$ for $\left|F_{\mathrm{o}}\right|>9 \cdot 0$; this showed no systematic dependence of $\left\langle w \Delta^{2}\right\rangle$ on $\left|F_{\mathrm{o}}\right|$ or $\sin \theta$.

Final observed and calculated structure factors are listed in Supplementary Publication No. SUP 20528 (11 pp., 1 microfiche).*

## RESULTS AND DISCUSSION

Final atomic co-ordinates and temperature-factor parameters, with their estimated standard deviations, are listed in Table 1. A view of the molecular conformation is shown in Figure 1, and the molecular dimensions and some intermolecular separations are provided in Table 2. Torsion angles for the rings are given in Figure 2, and dis-

[^2] 1970, Issue No. 20.
the conformation corresponding to (2b) becomes dominant when a benzene ring is fused at $C(5)-C(6)$, and the unfavourable diaxial interaction between the methoxycarbonyl and a $\mathrm{C}(5)$ hydrogen no longer exists. Relief from overcrowding which results from the adoption of conformation (2a) is achieved through a combination of factors (i) bond-length extension, (ii) bond-angle deformations, and (iii) flattening of the cyclohexane rings in the central region of the molecule. Ring bonds $C(1)-C(8 a)$ and $C(4 a)-C(8 a)$, mean $1.579 \AA$, are significantly longer than the other $\mathrm{C}\left(s p^{3}\right)-\mathrm{C}\left(s p^{3}\right)$ bonds (mean $1.539 \AA$ ) which are close

to the normal length ${ }^{8}[1 \cdot 537(5) \AA]$. Moreover, the exocyclic $\mathrm{C}(1)-\mathrm{C}(10)$ and $\mathrm{C}(1)-\mathrm{C}(14)$ bonds, mean $1.548 \AA$, are also significantly increased from the
${ }^{8}$ Chem. Soc. Special Publ., No. 18, 1965.
${ }^{9}$ B. E. Davison and A. T. McPhail, J. Chem. Soc. (B), 1970, 660.
normal length $\left[1-506(5) \AA\right.$ ] for $C\left(s p^{3}\right)-C\left(s p^{2}\right)$ bonds. Bond-angle deformation is apparent around $\mathrm{C}(1)$ and $\mathrm{C}(4)$ where $\mathrm{C}(10)-\mathrm{C}(1)-\mathrm{C}(14) 105 \cdot 5^{\circ}$ and $\mathrm{C}(5)-\mathrm{C}(4 \mathrm{a})-\mathrm{C}(9)$ $104.5^{\circ}$ are significantly smaller than the normal tetrahedral value ( $109 \cdot 5^{\circ}$ ) while $\mathrm{C}(8 \mathrm{a})-\mathrm{C}(1)-\mathrm{C}(14) 113 \cdot 4^{\circ}$ and $\mathrm{C}(8 \mathrm{a})-\mathrm{C}(4 \mathrm{a})-\mathrm{C}(9) \quad 112.7^{\circ}$ are enlarged. These angular changes serve to reduce the non-bonded interactions and the $\mathrm{C}(9) \cdots \mathrm{C}(14)$ distance is increased to $3 \cdot 10$ from the $2 \cdot 62 \AA$ separation of $\mathrm{C}(1) \cdots \mathrm{C}(4 \mathrm{a})$. The former distance

Figure 1 Molecular conformation and atomic numbering

Figure 2 Torsion angles (deg.) in the rings of one enantiomer
then becomes comparable to that of $3.03 \AA$ between diaxial carbon and oxygen atoms in methyl-4,6-O-benzylidene-2-O- $p$-bromobenzenesulphonyl-3-cyano-3-deoxy- $\alpha$-D-altropyranoside. ${ }^{9}$ Furthermore, torsion angles around the $C(4 a)-C(8 a)$ bond are smaller than average ( $55^{\circ}$ ) owing to flattening which occurs in the cyclohexane rings in order to reduce the 1,3 -diaxial interactions.
In the ester groups, the $\mathrm{C}(\alpha)-\mathrm{CO}-\mathrm{O}-\mathrm{C}(\mathrm{Me})$ atoms reveal the customary planarity (Table 5), and chemically equivalent bond lengths and valency angles are in excellent agreement. Mean dimensions are: $\mathrm{C}=\mathrm{O}_{1} 1 \cdot 204$, $\mathrm{C}\left(s p^{2}\right)-\mathrm{O} \quad 1 \cdot 336, \mathrm{C}\left(s p^{3}\right)-\mathrm{O} \quad 1 \cdot 453 \quad \AA$; $\mathrm{C}(\alpha)-\mathrm{C}=\mathrm{O} \quad 124 \cdot 3$, $\mathrm{C}(\alpha)-\mathrm{C}-\mathrm{O}(\mathrm{Me}) \quad 111 \cdot 6, \quad \mathrm{O}=\mathrm{C}-\mathrm{O}(\mathrm{Me}) \quad 124 \cdot 1, \quad \mathrm{C}-\mathrm{O}-\mathrm{C}(\mathrm{Me})$
$115 \cdot 5^{\circ}$. Dunitz and Strickler ${ }^{10}$ have recently discussed the preferred conformations of carboxylic acids, esters, and amides and have shown that a syn-planar orientation of the $\mathrm{C}=0$ bonds with respect to the $(\mathrm{C} \alpha)-\mathrm{C}(\beta)$ bonds is a common feature of these molecules. A similar arrangement is present in (2a) for which projections along the $\mathrm{C}(\alpha)-\mathrm{C}$ (carbonyl) bonds are illustrated in Figure 3. The larger value of the $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(14)-\mathrm{O}(16)$ torsion angle $\left(15^{\circ}\right)$ may arise from a small rotation of the axial ester

Figure 3 Torsion angles at the ester groups
group about the $\mathrm{C}(\mathbf{1})-\mathrm{C}(14)$ bond to reduce intramolecular non-bonded interactions.

A view of the molecular packing in the crystal is shown
