# Crystal and Molecular Structure of trans-2,trans-3-Dimethylcyclopropanecarboxylic Acid 

By P. A. Luhan and A. T. McPhail,* Paul M. Gross Chemical Laboratory, Duke University, Durham, North Carolina 27706, U.S.A.

Single-crystal $X$-ray analysis of the title compound has established its constitution and molecular dimensions. Crystals are monoclinic, space group $P 2_{1} / c$, with $Z=4$, in a cell of dimensions: $a=6 \cdot 39, b=10 \cdot 98, c=9.76 \AA$, $\beta=105 \cdot 6^{\circ}$. The structure was solved by direct phase-determining methods and refined by full-matrix leastsquares calculations to $R 0.085$ over 638 reflections. The crystals contain centrosymmetric hydrogen-bonded dimers with a conformation in which the $\mathrm{C}=\mathrm{O}$ bond points over the cyclopropane ring.

During their investigations on the mechanism of cyclopropane formation from epoxides via the Wittig reaction, Ghirardelli and Izydore ${ }^{1}$ obtained mixtures of isomeric 2,3-dimethoxycyclopropanecarboxylic acids, (I)-(III), from reactions involving $(+)-(2 R, 3 R)-2,3$-epoxybutane and cis-2,3-epoxybutane. In order that an analysis of the reaction mechanism could be made, it was imperative that the identity of each isomer be established unequivocally. The constitution of (I) was inferred from its optical activity. One of the other two isomers was isolated from the product mixture as a solid, m.p. $79-80 \cdot 5^{\circ}$, and we have subjected it to single-crystal
${ }^{1}$ R. G. Ghirardelli and R. A. Izydore, personal communication.
$X$-ray analysis to determine its configuration We here report the results of this analysis.

## EXPERIMENTAL

Crystal Data.- $\mathrm{C}_{6} \mathrm{H}_{10} \mathrm{O}_{2}$, m.p. 79-80.5 ${ }^{\circ}, \quad M=114 \cdot 1$. Monoclinic, $\quad a=6.39(1), \quad b=10.98(2), \quad c=9.76(2) \quad \AA$, $\beta=105 \cdot 6(2)^{\circ}, \quad U=660 \AA^{3}, \quad D_{\mathrm{m}}=1 \cdot 14, \quad Z=4, \quad D_{\mathrm{c}}=$ 1.148, $\quad F(000)=248 . \quad \mathrm{Cu}-K_{\alpha}$ radiation $\lambda=1.542 \AA$, $\mu\left(\mathrm{Cu}-K_{\alpha}\right)=7 \cdot 1 \quad \mathrm{~cm}^{-1}$. Space group $P 2_{1} / c \quad\left(C_{2 h}^{5}\right)$ from systematic absences: $0 k 0$ when $k \neq 2 n$ and $h 0 l$ when $l \neq 2 n$.

Crystallographic Measurements.-The crystals have a tendency to sublime at room temperature, and so those used for the data collection were sealed in thin-walled glass capillaries. Unit-cell dimensions were evaluated from
precession photographs taken with Mo- $K_{\alpha}(\lambda=0.7107 \AA)$ radiation. Intensities were estimated visually from equiinclination multiple-film Weissenberg photographs of the layers $0-6 k l$ taken with $\mathrm{Cu}-K_{\alpha}$ radiation. Spot-shape

(III)
corrections and the usual Lorentz and polarization factors were applied, and 638 independent observed structure amplitudes were obtained. No allowance was made for absorption.

Structure Analysis.--The structure was solved by direct phase-determining methods. ${ }^{2}$ Initially, three origin-defining reflections were assigned phases, $2,2,1,|E|=2 \cdot 48$, $\phi=0 ; 1,3,2,|E|=2 \cdot 47, \phi=0 ; 4,7, \overline{2},|E|=2 \cdot 46, \phi=0$, and one further reflection $4,11, \overline{1},|E|=2.25$ was assigned $\phi=a$. These four reflections were expanded into a set of ten reflections for which $\left|E_{H} \cdot E_{K} \cdot E_{H-K}\right|>10 \cdot 0$. By use of a local version of the iterative program of Drew ${ }^{3}$ as amended by Larson and Motherwell ${ }^{4}$ the tangent formula ${ }^{5}$ was applied to this basis set to generate the phases for other reflections. The phase $a$ was allowed to assume values of 0 and $\pi$ and the largest $120|E|$ values were refined for four cycles and 200 were refined for five cycles. In any cycle a phase assignment was rejected if the consistency index, $t=\sqrt{A^{2}+B^{2}} / \Sigma_{K}\left|E_{K} \cdot E_{H-K}\right|$ was $<0.30$ and the value of $\alpha=\left|E_{H}\right| \sqrt{A^{2}+B^{2}}$ was $<3 \cdot 0$. A summary of the results of the refinement are presented in Table 1, which

Table 1
Summary of output from tangent refinement

|  |  |  |  | No. of | No. of <br> phases |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $a$ | $t$ | $\alpha$ | $R_{K}$ | $\Sigma_{2}$ values | assigned |
| 0 | 0.87 | 58 | 0.04 | 2211 | 185 |
| - | 0.77 | 48 | 0.15 | 2029 | 176 |

shows that the set with $a=0$ has a markedly lower $R_{K}\left[=\Sigma_{H}\left|E_{H}\right|_{\text {obs }}-\left.\left|E_{H}\right|_{\text {cale }}\left|/ \Sigma_{H}\right| E_{H}\right|_{\text {obs }}\right]$ value. In the $E-$ map computed by use of the phases derived from the set with $R_{K} 0.04$, all non-hydrogen atoms appeared in chemically reasonable positions. The $E$-map based on the other set contained no recognizable features. The approximate atomic positions derived from the $E$-map, all with $B 3.5 \AA^{2}$, were used to compute structure factors for which $R$ was 0.378 . The positional and isotropic thermal parameters were then refined for seven cycles of full-matrix least-

${ }^{2}$ J. Karle and I. L. Karle, Acta Cryst., 1966, 21, 849.
${ }^{3}$ See. e.g., M. G. B. Drew, D. H. Templeton, and A. Zalkin, Acta Cryst., 1969, B, 25, 261.
squares calculations which reduced $R$ to $0 \cdot 176$. Calculation of a three-dimensional difference electron-density map indicated that there was significant density at all positions calculated for the hydrogen atoms assuming $\mathrm{C}-\mathrm{H} 1.07$ and $\mathrm{O}-\mathrm{H} 1 \cdot 0 \AA$. The ten hydrogen atoms were included, with $B 5 \cdot 0 \AA^{2}$ in the next eight rounds of least-squares calculations during which carbon and oxygen atomic positional and anisotropic thermal parameters were adjusted. These decreased $R$ to 0.094 . In a further three least-squares cycles the hydrogen positional and isotropic thermal parameters were varied, and the refinement converged at $R 0.085$.
For all the structure-factor calculations, scattering factors for neutral atoms were taken from ref. 6. The weighting scheme for the least-squares calculations was $\sqrt{ } w=1$ for $\left|F_{\mathrm{o}}\right| \leqslant 5 \cdot 5$ and $\sqrt{ } w=\left|F_{\mathrm{o}}\right| / 5 \cdot 5$ for $\left|F_{\mathrm{o}}\right|>5.5$, and $\Sigma w \Delta^{2}$ was minimized. At the conclusion of the refinement, analysis of $\left\langle w \Delta^{2}\right\rangle$ in ranges of $\left|F_{0}\right|$ and $\sin \theta$ indicated the adequacy of this scheme.
Final observed and calculated structure factors are listed in Supplementary Publication No. SUP 20527 ( 6 pp., 1 microfiche).*

## RESULTS AND DISCUSSION

This $X$-ray analysis defines (III) as the constitution of the acid studied, whence the third isomeric acid must have configuration (II).

## Table 2

Roman numeral superscripts refer to the following transformations of the co-ordinates of Table 2:

$$
\begin{array}{ll}
\text { I } 2-x, \text { I }-y, 1-z & \text { III } 1-x, \frac{1}{2}+y, \frac{1}{2}-z \\
\text { II } 1+x, \frac{1}{2}-y, \frac{1}{2}+z & \text { IV } 2-x, \frac{1}{2}+y, \frac{1}{2}-z
\end{array}
$$

projected along the $b$-axis is shown in the Figure. In the crystal the acid molecules exist as centrosymmetric hydrogen-bonded dimers with $\mathrm{O}-\mathrm{H} \cdot \mathrm{O} 2.65 \AA$. The dimers are separated from each other by normal van der Waals distances with the closest interdimer separation at $3.45 \AA$ occurring between a carboxyl oxygen atom of the reference molecule and a methyl carbon atom of a molecule related by the $c$ glide plane operation.

The cyclopropane ring dimensions accord well with those for other similar systems studied by $X$-ray diffraction. In cyclopropanecarbohydrazide, ${ }^{7}$ cyclopropanecarboxamide, ${ }^{8}$ and cyclopropane-1,1-dicarboxylic acid, ${ }^{9}$ the endocyclic angle at the carbon atom bearing the substituent is smaller than at the other two which are not

[^0]significantly different, and, correspondingly, the bond length opposite the smallest angle is the shortest. This situation holds true also in (III), for the internal angle at $\mathrm{C}(1)$ is $58.3^{\circ}$ and $\mathrm{C}(2)-\mathrm{C}(3) 1 \cdot 478 \AA$, significantly smaller than the mean $(1.516 \AA)$ for the other ring bonds. The mean cyclopropane $C-C$ distance $(1.503 \AA)$ is smaller than the normal length in saturated hydrocarbons ${ }^{10}$ [1.537(5) $\AA]$, but is in excellent agreement with the corresponding mean in other crystalline simple cyclopropane derivatives studied ( 1.50 in cyclopropanecarbohydrazide ${ }^{7}$ and cyclopropanecarboxamide, ${ }^{8} \quad 1.510$ in cyclopropane-1,1dicarboxylic acid, ${ }^{9}$ and $1.507 \AA$ in bicyclopropyl ${ }^{11}$ at $-105{ }^{\circ} \mathrm{C}$ ), and only slightly shorter than the $1.518 \AA$ in cis-1,2,3-tricyanocyclopropane. ${ }^{12}$ The cyclopropane C-C

The crystal structure viewed in projection along the $b$ axis. Hydrogen bonds are denoted by broken lines
length from an electron diffraction study ${ }^{13}$ is $1.510 \AA$. There have been numerous discussions in the literature to account for the physical and chemical properties of cyclopropane and its derivatives with either the CoulsonMoffitt ${ }^{14}$ 'bent' bond model or Walsh's ${ }^{15} \pi$-electron model being favoured.

The dihedral angle between the planar carboxy-group and the cyclopropane ring is $85^{\circ}$, similar to the values of 88.0 and $88.3^{\circ}$ in two crystallographically independent molecules of cyclopropanecarboxamide, ${ }^{8} 88.5^{\circ}$ in cyclopropanecarbohydrazide, ${ }^{7}$ and $86 \cdot 2,86 \cdot 7,87 \cdot 6$, and $88 \cdot 6^{\circ}$ at the carboxy-groups in two molecules of cyclopropane-1,1-dicarboxylic acid. ${ }^{9}$ In the carboxy-group the identity of the carbonyl oxygen atom, $\mathrm{O}(8)$, is consistently

## Table 4

Torsion angles (deg.) around exocyclic $\mathrm{C}-\mathrm{C}$ bonds in some cyclopropane derivatives

established ${ }^{16}$ from the short $\mathrm{C}(4)-\mathrm{O}(8)$ bond length, the pattern of angles around $\mathrm{C}(4)$, and the location of the hydroxy-hydrogen atom $0.92 \AA$ from $\mathrm{O}(7)$. The carbonyl
oxygen atom lies over the cyclopropane ring, but it is not equidistant from C(2) and C(3) (Table 3). A survey of the torsion angles around the exocyclic $\mathrm{C}-\mathrm{C}$ bonds in simple cyclopropane derivatives (Table 4) shows that in all of these the torsion angles are unequal and there is a significant departure from $C$ s symmetry. Electron diffraction patterns of cyclopropanecarbaldehyde ${ }^{17}$ have been interpreted on the basis of about $50 \%$ population of the $C_{s}$-cis-configuration in the vapour phase.

We thank Drs. R. G. Ghirardelli and R. A. Izydore for suggesting this problem and for crystals, and the Army Research Office, Durham, for partial support of this work. All calculations were performed on the IBM 370/165 computer located at the Triangle Universities Computation Centre, Research Triangle Park, North Carolina.
