# Crystal Structure of Di-p-tolylcarbodi-imide, $\mathrm{MeC}_{6} \mathrm{H}_{4} \cdot \mathrm{~N}: \mathrm{C}: \mathrm{N}^{\mathrm{N}} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me} \dagger$ 

By A. T. Vincent and P. J. Wheatley,* Department of Physical Chemistry, Lensfield Road, Cambridge CB2 1 EP

Crystals of the title compound are orthorhombic with $a=11 \cdot 310, b=14.799, c=7.690 \AA, Z=4$, space group $P 2_{1} 2_{1} 2_{1}$. 1511 Visually estimated $X$-ray reflexions were refined by least squares to $R 6 \cdot 25 \%$; the structure was solved by direct methods. The stereochemistry of the molecule is of the allene type with the two $\mathrm{C}-\mathrm{N}=\mathrm{C}$ planes approximately normal to each other, with $\mathrm{C}-\mathrm{N}=\mathrm{C}$ angles of $127 \cdot 2(3)$ and $128 \cdot 4(3)^{\circ}$, and with an $\mathrm{N}=\mathrm{C}=\mathrm{N}$ angle of $170 \cdot 4(4)^{\circ}$.

In earlier work, dipole-moment messurements were used to predict the stereochemistry of carbodi-imides $\mathrm{R}^{1} \mathrm{~N}: \mathrm{C}: \mathrm{NR}^{2}$. Bergmann and Schütz ${ }^{1}$ interpreted their results in terms of a linear structure for $N N^{\prime}$-disubstituted carbodi-imides. However, Schneider ${ }^{2}$ suggested that a three-dimensional asymmetrical structure was equally compatible with the observed results. More recently, Feichtmayr and Würstlin ${ }^{3}$ have made further dipole-moment measurements and have concluded that carbodi-imides have allene-type structures which should exist as enantiomorphs with the planes containing $\mathrm{R}^{1}$ and $\mathrm{R}^{2}$ normal to each other. Vinylideneamines, containing the C:C:N group, often show anomalous values for the angle at the nitrogen atom with variations from $123-180^{\circ} .{ }^{4-7}$ The structure of di- $p$-tolylcarbodi-imide has been determined to see if the molecule assumed the configuration predicted from classical stereochemistry or shows unpredictable angles as do the vinylideneamines. The only previous structural determination of an $N N^{\prime}$-disubstituted carbodiimide had shown the $\mathrm{C} \cdot \mathrm{N}: \mathrm{C}: \mathrm{N} \cdot \mathrm{C}$ chain to be bent at the nitrogen atoms but no angles were reported as only the $h k 0$ projection was solved. ${ }^{8}$

## EXPERIMENTAL

Crystal Data.- $\mathrm{C}_{15} \mathrm{H}_{14} \mathrm{~N}_{2}, \quad M=222 \cdot 3$, Orthorhombic, $a=11 \cdot 310(8), b=14 \cdot 799(10), c=7 \cdot 690(7) \AA, U=1287 \cdot 1$ $\AA^{3}, D_{\mathrm{m}}=1 \cdot 15, Z=4, D_{\mathrm{c}}=1 \cdot 148, F(000)=472$. Space group $P 2_{1} 2_{1} 2_{1}$. Cu- $K_{\alpha}$ radiation, $\lambda=1.5418 \AA, \mu\left(\mathrm{Cu}-K_{\alpha}\right)$ $=5 \cdot 4 \mathrm{~cm}^{-1}$.

Cell dimensions were obtained from oscillation and Weissenberg photographs and agreed well with values previously determined. ${ }^{8}$ Intensities were collected from equi-inclination Weissenberg photographs of the $h k 0-7$ and $0-10 k l$ layers and estimated visually. The same crystal was used for both sets of measurements. 1511 Independent reflexions were assigned non-zero intensity and were corrected for Lorentz and polarisation effects, but not for absorption. The intensities were placed on the same scale through common reflexions. The 002 reflexion was noted to have the strongest intensity but, due

[^0]to its diffuseness, a satisfactory intensity measurement could not be made.

Structure Determination and Refinement.-The structure was solved by direct methods. Three phases were chosen to determine the origin (parity groups $g u u, g g u$, and $u g u$ ) and a fourth phase (parity group ggu, to give a structure invariant) to select the enantiomorph. Two planes were chosen from the parity groups gug and uug, and the four possible combinations of their phases used as a starting set together with the origin- and enantiomorph-determining phases. Six cycles of least-squares refinement ( 60 planes) and twelve cycles of tangent refinement ( 211 planes with $E>1.45$ ) were used for each of the four starting sets of phases. $E$-maps were calculated in each case from the 211 reflexions with their refined phases. One such map could be interpreted in terms of a partial structure consisting of one phenyl group with substituent atoms in the 1 - and 4 -positions, and two atoms which appeared to be part of the other phenyl group. A complete structure was derived from this information, and full-matrix leastsquares refinement ( $\mathbf{3 8 5}$ planes) reduced $R$ to $\mathbf{1 5 \cdot 2 \%}$ with a single isotropic thermal factor. Refinement was continued with the full data set, with isotropic thermal factors for the nitrogen and carbon atoms, and the secondary extinction coefficient ${ }^{9}$ as a refineable parameter. At $R \mathbf{1 2 . 4} \%$ phenyl group hydrogen atoms were introduced at calculated positions, new positions being obtained before each subsequent refinement cycle. Anisotropic refinement of the non-hydrogen atoms with an overall thermal factor for each group of phenyl hydrogen atoms reduced $R$ to $\mathbf{7 . 7 5 \%}$. A difference Fourier synthesis was then calculated in an attempt to locate the methyl hydrogen atoms. Six peaks at chemically reasonable positions were found, but they were somewhat diffuse. Three of the hydrogen atoms refined satisfactorily, but it was necessary to fix the others at stereochemically reasonable positions all of which were within the regions of electron density found on the diffrence map. Further refinement cycles with a fixed thermal factor for the methyl hydrogen atoms yielded a final $R$ of $6.25 \%$. The final mean shift to $\sigma$ ratio was 0.012 for all parameters.

The weighting scheme ${ }^{10}$ was $w=1 /\left(0.74+F_{0}+\right.$ $0.03 F_{0}{ }^{2}$ ) with the constants chosen from an analysis of the variance. Scattering factors ${ }^{11}$ were used in which the imaginary part was set equal to zero. Friedel's law was

[^1]assumed in the data reduction, and no attempt was made to determine the absolute configuration.

## RESULTS

The final fractional co-ordinates, anisotropic and isotropic temperatute factors, with their estimated standard deviations given as units in the last place, are listed in Tables

Table 1
(a) Final fractional co-ordinates ( $\times 10^{4}$ ) for the heavier atoms with estimated standard deviations in parentheses

1 and 2. The thermal factors for the two methyl carbon atoms are considerably higher than for the carbon atoms to which they are attached. No correction for thermal motion has been applied to the bond lengths and angles. An analysis of the agreement between observed and calculated structure factors is given in Table 3. A similar analysis in terms of parity groups shows a very even distribution in terms of both the number of reflexions and the values of $R$. A Table of observed and calculated structure factors is published in Supplementary PublicaNo. SUP 20330 ( 15 pp., 1 microfiche).* The labelling of the atoms is shown in Figure 1.

* For details of Supplementary Publications see Notice to Authors No. 7 in J. Chem. Soc. (A), 1970, Issue No. 20.

Bond lengths and angles are listed in Table 4. The mean C-C length in the phenyl groups ( 1.387 and $1.385 \AA$ ) is slightly less than the standard value $(1 \cdot 394 \AA) .1^{12}$ The bond lengths between the nitrogen and carbon atoms are

very similar to the corresponding lengths in two vinylideneamines ${ }^{7}$ which have approximately the same angle at the nitrogen atom. The difference between the $\mathrm{C}(1)-\mathrm{N}(1)$ and $\mathrm{C}(1)-\mathrm{N}(2)$ lengths appears to be significant (4б). The $\mathrm{N}(1)-\mathrm{C}(11)$ and $\mathrm{N}(2)-\mathrm{C}(21)$ lengths are significantly less than the single-bond value $(1 \cdot 475 \AA) .{ }^{12}$ The angle at the central carbon atom $\left(170 \cdot 4^{\circ}\right)$ shows a distortion from the ideal value which is probably due to packing forces and is commonly found in cumulenes. ${ }^{5-7,13}$

closer to the plane of the phenyl group in 4 than in 3 . This feature is emphasised by the torsion angles quoted in Table 6 . The torsion angle $\mathrm{C}(11)-\mathrm{N}(1)-\mathrm{N}(2)-\mathrm{C}(21)$ would be $90^{\circ}$ for an idealised allene-type structure.
The number and the shortest of the van der Waals contacts are given in Table 7. The packing of the molecules is shown in Figure 2. The crystal structure is layered

Table 5
Least-squares planes in terms of orthogonal axes coincident with the crystal axes. Deviations ( $\AA$ ) of relevant atoms from the phases are given in square brackets

| $\mathrm{H}(\mathrm{Me}) \cdots \mathrm{H}(\mathrm{Me})$ | 2 | $3 \cdot 4$ | $3 \cdot 023$ |

## DISCUSSION

This $X$-ray structure determination shows that di-$p$-tolylcarbodi-imide has approximately the stereochemistry expected on classical grounds. The angles at the nitrogen atoms are close to those expected for
trigonal hybridisation. This feature, together with the torsion angle ( $88^{\circ}$ ) defined by $\mathrm{C}(11)-\mathrm{N}(1)-\mathrm{N}(2)-\mathrm{C}(21)$, gives the molecule an allene-type configuration. The orientation of the phenyl groups relative to the respective $\mathrm{C}-\mathrm{N}=\mathrm{C}$ planes suggests that some conjugation may be taking place between the phenyl groups and the cumulene chain. The $\mathrm{C}-\mathrm{N}$ lengths are short and nearly the same. There is, however, a significant difference between the $\mathrm{C}=\mathrm{N}$ lengths ( $\mathbf{1} \cdot 223$ and $1.204 \AA$ ) which can be correlated with the difference in torsion angles ( 19.8 and $7.9^{\circ}$ ). The comparison with the vinylideneamines provides further consistent information about the relationship between the $\mathrm{N}=\mathrm{C}$ and $\mathrm{N}-\mathrm{C}$ bond lengths and the value of the angle at the nitrogen atom. ${ }^{7}$

We thank Dr. G. M. Sheldrick for the use of his computer programmes, the University Computer Laboratory for facilities, and the S.R.C. for the provision of equipment and for a maintenance grant (to A. T. V.).
