## Crystal Structures of the Acid Salts of Some Monobasic Acids. Part XV. ${ }^{1}$ Potassium Hydrogen Diacetate

By Murdoch Currie,* Chemistry Department, The University, Glasgow G12 800, Scotland
The crystal structure of the title compound $\mathrm{KH}(\mathrm{AcO})_{2}$ has been determined by $X$-ray analysis and solved by the heavy-atom method. $Z=4$ in a monoclinic unit cell of dimensions $a=4 \cdot 085, b=23 \cdot 84, c=7 \cdot 226 A, \beta=97 \cdot 4^{\circ}$, space group is $P 2_{1} / n$. Refinement by anisotropic least-squares analysis has led to a final $R$ of 0.106 for 849 data. This acid salt proves to be of Type $B$, i.e. the residues AcOH and $\mathrm{AcO}{ }^{-}$are crystallographically distinct: these residues are linked through a short unsymmetrical hydrogen bond. with $0 \cdots O 2 \cdot 476$ (8) A.

THE acid sodium, potassium, and ammonium salts of acetic acid have totally different crystal structures. In the sodium salt, ${ }^{2} \mathrm{NaH}(\mathrm{AcO})_{2}$, the $\mathrm{H}(\mathrm{AcO})_{2}{ }^{-}$anion has crystallographic symmetry, and hence is of Type $A .^{3}$ The ammonium salt ${ }^{4}$ has a more complex structure, better

[^0]represented by the formula $\left[\mathrm{NH}_{4}{ }^{+} \mathrm{H}(\mathrm{AcO})_{2}{ }^{-},\left(\mathrm{NH}_{4}{ }^{+}\right.\right.$ $\left.\left.\mathrm{AcO}^{-}, \mathrm{AcOH}\right)_{2}\right]$. The $\mathrm{H}(\mathrm{AcO})_{2}{ }^{-}$anion has a symmetrical hydrogen bond (Type $A$ ), whilst the bond between $\mathrm{AcO}^{-}$and AcOH is unsymmetrical (Type $B$ ). The $X$-ray analysis of potassium hydrogen diacetate,

[^1]$\mathrm{KH}(\mathrm{AcO})_{2}$, which is now reported, shows the structure of this crystal to be of Type $B$, as had been suggested by its i.r. spectrum.

## EXPERIMENTAL

Potassium hydrogen diacetate was prepared by heating an aqueous solution of potassium hydroxide ( 1 mol ) and acetic acid $(2 \mathrm{~mol})$. The crystals were difficult to handle, tending to lose acetic acid, and were deliquescent. A crystal of dimensions $c a .0 .60 \times 0.25 \times 0.15(\mathrm{~mm})$ had therefore to be enclosed in a capillary tube in order that $X$-ray measurements could be made.

The cell dimensions were established by means of a least-squares refinement of the positions of a number of reflexions as determined on a Hilger and Watts Y 290, computer-controlled, four-circle diffractometer by use of a Zr -filter to give $\mathrm{Mo}-K_{\alpha}$ radiation $(\lambda=0.71069 \AA ; \quad 1 \AA=$ 100 pm ).

Crystal Data. $-\mathrm{KH}\left(\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{O}_{2}\right)_{2}, \quad M=158 \cdot 2$, Monoclinic, $a=4 \cdot 085(5), b=23 \cdot 84(4), c=7 \cdot 226(7) \AA, \beta=97 \cdot 4^{\circ}\left(0 \cdot 1^{\circ}\right)$, $U=697.75 \AA^{3}, Z=4, D_{\mathrm{c}}=1.506 . \quad \mu\left(\mathrm{Mo}-K_{\alpha}\right)=6.96 \mathrm{~cm}^{-1}$. Space group $P 2_{1} / n\left(C_{2 h}^{5}\right)$; no molecular symmetry required.

The intensities of 1226 independent reflexions ( $0-h$, $0-k, l-l)$ out to $\theta=25^{\circ}$ were measured on the diffractometer by use of $\mathrm{Mo} K_{\alpha}$ radiation. An $\omega-2 \theta$ scan was carried out ( 80 steps of $0.01^{\circ}, 1 \mathrm{~s}^{-1}$ ) and 20 s were spent on each of two background counts.

Corrections for the Lorentz and polarization factors were applied to the intensities, but none was made for absorption, which was assumed to be negligible.

Structure Solution and Refinement.-The structure was solved by the heavy-atom method. Electron-density syntheses, based on $\mathrm{K}^{+}$only, enabled the location of all the remaining non-hydrogen atom positions.

Four cycles of full-matrix, least-squares refinement, with isotropic vibrational parameters and unit weights, reduced $R$ from 0.282 to $0 \cdot 202$. At this stage a difference synthesis was computed, but no significant electron density was found where hydrogen atoms would be expected. After a further three cycles of least-squares refinement, with anisotropic vibrational parameters and unit weights, $R$ was reduced to $0 \cdot 141$. For the final five cycles of refinement all data with $I<3 \sigma(I)$ were excluded, and a weighting scheme introduced, such that $w=1$ for $\left|F_{0}\right|<p$, and $w=\left(\frac{p}{\left|F_{\mathrm{o}}\right|}\right)^{2}$ for $\left|F_{o}\right|>p$; the final value of $p$ was 10 . Refinement converged with $R 0.106$ and $R^{\prime} 0.015\left(R^{\prime}=\Sigma w \Delta^{2} / \Sigma w\left|F_{\mathrm{o}}\right|^{2}\right)$ for 849 data. Atom scattering factors for potassium, oxygen, and carbon were taken from ref. 5. Observed structure amplitudes and calculated structure factors are listed in Supplementary Publication No. SUP 20349 (2 pp., 1 microfiche).* Table 1 gives an analysis of the agreement between $\left|F_{o}\right|$ and $\left|F_{\mathrm{c}}\right|$. It supports the general validity of the weighting scheme used.

The atomic co-ordinates are listed in Table 2, and vibrational parameters in Table $\mathbf{3}$ (estimated standard deviations were derived from the inverse of the leastsquares matrix).

## DISCUSSION

The Figure shows the structure in its $a$ axial projection. The atoms numbered constitute the crystal-

chemical unit (CCU); ${ }^{6}$ other symmetry-related units are denoted as follows:

$$
\begin{aligned}
\text { CCU } x, y, z & \text { III } \frac{1}{2}+x, \frac{1}{2}-y,-\frac{1}{2}+z \\
\text { I }-1+x, y, z & \text { IV }-\frac{1}{2}+x, \frac{1}{2}-y,-\frac{1}{2}+z \\
\text { II } x, y,-1+z &
\end{aligned}
$$

In an acid salt of Type $B$, in which there are two nonequivalent residues, one should be recognisable as the neutral molecule AcOH and the other as the anion $\mathrm{AcO}^{-}$; this distinction is apparent in potassium hydrogen

[^2]diacetate (Table 4). In one residue, comprising $C(1)$, $\mathrm{C}(2), \mathrm{O}(1)$, and $\mathrm{O}(2)$, the $\mathrm{C}-\mathrm{O}$ distances differ by $0.079 \AA$, and the $\mathrm{C}-\mathrm{C}-\mathrm{O}$ angles by $7.9^{\circ}$, and it may be concluded that this is the uncharged molecule AcOH . In the other

Table 4
Interatomic distances ( $\AA$ ) and bond angles (deg.), with standard deviations in parentheses

| (a) Distances |  |  |  |
| :--- | :--- | :--- | :--- |
| $\mathrm{C}(1)-\mathrm{C}(2)$ | $1.510(13)$ | $\mathrm{C}(11)-\mathrm{C}(12)$ | $1.491(12)$ |
| $\mathrm{C}(1)-\mathrm{O}(1)$ | $1.211(10)$ | $\mathrm{C}(11)-\mathrm{O}(11)$ | $1.247(9)$ |
| $\mathrm{C}(1)-\mathrm{O}(2)$ | $1 \cdot 290(10)$ | $\mathrm{C}(11)-\mathrm{O}(12)$ | $1 \cdot 268(9)$ |
| $\mathrm{O}(2) \cdots \mathrm{O}(12)$ | $2 \cdot 476(8) \AA$ |  |  |
| $(b)$ Angles |  |  |  |
| $\mathrm{O}(1)-\mathrm{C}(1)-\mathrm{O}(2)$ | $123 \cdot 5(8)$ | $\mathrm{O}(11)-\mathrm{C}(11)-\mathrm{O}(12)$ | $121 \cdot 2(7)$ |
| $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{O}(2)$ | $114 \cdot 3(7)$ | $\mathrm{C}(12)-\mathrm{C}(11)-\mathrm{O}(12)$ | $119 \cdot 5(7)$ |
| $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{O}(1)$ | $122 \cdot 2(8)$ | $\mathrm{C}(12)-\mathrm{C}(11)-\mathrm{O}(11)$ | $119 \cdot 3(6)$ |
|  |  | $\mathrm{C}(1)-\mathrm{O}(2) \cdots \cdot \mathrm{O}(12)$ | $115 \cdot 6(5)$ |
|  |  | $\mathrm{C}(11)-\mathrm{O}(12) \cdots \mathrm{O}(2)$ | $115 \cdot 0(5)$ |

residue, comprising $\mathrm{C}(11), \mathrm{C}(12), \mathrm{O}(11)$, and $\mathrm{O}(12)$, the $\mathrm{C}-\mathrm{O}$ distances differ by only $0.021 \AA$, and the $\mathrm{C}-\mathrm{C}-\mathrm{O}$ angles by only $0 \cdot 2^{\circ}$, which leads to the conclusion that this residue is the carboxylate ion $\mathrm{AcO}^{-}$. A similar situation is found in other acid salts of Type $B$, e.g. rubidium hydrogen di(glycollate), ${ }^{7}$ and in acid salts of Type $B_{2}$, e.g. sodium hydrogen oxalate monohydrate. ${ }^{8}$

The AcOH and $\mathrm{AcO}^{-}$residues are linked through a non-symmetrical hydrogen bond, $\mathrm{O}(2) \cdots \mathrm{O}(12)$ $2 \cdot 476(8) \AA$. This may be compared with $\mathrm{O} \cdots \mathrm{O}$
carbon atoms, and are similar to those found ${ }^{2}$ in $\mathrm{NaH}(\mathrm{AcO})_{2}(1.49 \AA)$ and in the ammonium salt ${ }^{4}$ (mean $1.50 \AA$ ). A comparison with the corresponding bond in potassium hydrogen bis(trifluoroacetate), ${ }^{1}$ C-C $1.543 \AA$ (neutron-diffraction analysis), shows that the substitution of the methyl group by a trifluoromethyl group

The crystal structure of potassium hydrogen diacetate in its $a$ axial projection
causes a lengthening of the $\mathrm{C}-\mathrm{C}$ bond; a similar effect is found when ammonium acetate ${ }^{10}$ (C-C 1.504 $\AA$ ) and ammonium trifluoroacetate ${ }^{11}$ (C-C $1.535 \AA$ ) are compared.
The potassium ion makes contact with seven oxygen atoms. The $\mathrm{K}^{+} \cdots \mathrm{O}$ distances, which are all $<\mathbf{3} \cdot \mathbf{0} \AA$, are given in Table 5 along with the $\mathrm{O} \cdots \mathrm{K}^{+} \cdots \mathrm{O}$ angles.

* $\sigma \leqslant 0 \cdot 2^{\circ}$.
distances of $2 \cdot 444(10) \AA$ (Type $A$ ) in $\mathrm{NaH}(\mathrm{AcO})_{2},{ }^{2}$ and of $2 \cdot 474(6) \AA$ (Type $A$ ) and $2 \cdot 517(4) \AA$ (Type $B$ ) in the ammonium salt. ${ }^{4}$

The non-hydrogen atoms of each residue are virtually coplanar. The equation of the plane through AcOH is $-0.8863 X^{\prime}-0.0921 Y-0.4539 Z^{\prime}=-2.885 \AA$, and the maximum deviation from it is $0.002 \AA$ for $\mathrm{C}(1)$. The equation of the plane through $\mathrm{AcO}^{-}$is $-0.9222 X^{\prime}+$ $0.0741 Y-0.3796 Z^{\prime}=-2.052 \AA$, with a maximum deviation from it of $0.007 \AA$ for $\mathrm{C}(11)$.

The $\mathrm{C}-\mathrm{C}$ distances, $\mathrm{C}(1)-\mathrm{C}(2) 1.510(13)$ and $\mathrm{C}(11)-\mathrm{C}(12)$ $1-491(12) \AA$, do not significantly differ from the length $1.505 \AA$ suggested ${ }^{9}$ for a single bond between $s p^{3}$ and $s p^{2}$

[^3]${ }^{10}$ I. Nahringbauer, Acta Cryst., 1967, $23,956$.

There are no unusual non-bonded intermolecular contacts in the structure, the shortest being $\mathrm{O}(2) \cdots \mathrm{C}\left(2^{\mathrm{I}}\right)$ 3.481 and $\mathrm{O}(1) \cdots \mathrm{C}\left(12^{\text {II }}\right) 3 \cdot 526 \AA$.

The very different crystal structures of the acid sodium, potassium, and ammonium salts of acetic acid are not surprising in view of the relatively small size of the acid residues. It is generally found that, when the acid residue is large, it dominates the crystal structure, e.g. potassium, ammonium, and rubidium hydrogen bis- $(p \text {-chlorobenzoate })^{12}$ are all isomorphous. Indeed, even changing the position of the chlorine atom in the phenyl ring has little effect, and the crystal structures of potassium hydrogen bis- $(p$-chlorobenzoate) and potassium

[^4]hydrogen bis-( $m$-chlorobenzoate) are remarkably similar. ${ }^{13}$ In contrast, the crystal structures of the acid lithium, ${ }^{14}$ sodium, ${ }^{8}$ and potassium ${ }^{15}$ salts of oxalic acid, the simplest of the dibasic acids, all differ considerably from one another.

I thank D. Woodhouse for help with the data collection and Drs. A. L. Macdonald and J. C. Speakman for valuable
discussions. The KDF9 programs used were those developed by D. W. J. Cruickshank, J. G. Sime, K. W. Muir, and others.
