## Thermodynamic Analysis of Substituent Effects on Proton Dissociation Equilibria of Substituted Pyridines

By Ignazio R. Bellobono * and Mario A. Monetti, Istituto Chimico, Università di Roma, 00185 Rome and Istituto di Chimica Fisica, Università di Milano, 20133 Milan, Italy

Equilibrium constants for the dissociation of $\mathrm{RC}_{5} \mathrm{H}_{4} \mathrm{NH}^{+}\left(\mathrm{R}=3\right.$ - and $4-\mathrm{Br}, 3-$ and $4-\mathrm{CN}$, and 2- and 3- $\mathrm{NH}_{2}$ ) have been measured as a function of temperature in the range $5-65^{\circ} \mathrm{C}$. For these and other literature data ( $\mathrm{R}=\mathrm{H}, 2-, 3-$, and $4-\mathrm{NO}_{2}, 2-, 3-$, and $4-\mathrm{Me}, 2-, 3-$, and $4-\mathrm{CHO}, 2-, 3-$, and $4-\mathrm{Ac}, 2-\mathrm{CH}_{2} \mathrm{NHMe}^{2}$, and $4-\mathrm{NH}_{2}$ ) thermodynamic functions ( $\Delta G^{0}, \Delta H^{0}$, and $\Delta S^{0}$ ) have been calculated by a thermodynamic optimization method and by the Clarke and Glew procedure. Substituent effects, the environmental parameter for the reaction series examined, and solvent-solute interactions are discussed on the basis of Hepler's dichotomized enthalpy-entropy model, and the approach developed by Bolton et al.

Recent investigations ${ }^{1-4}$ of thermodynamics of acidbase equilibria in terms of a dichotomized enthalpyentropy model ${ }^{5-8}$ have led to useful information about interpretation of substituent effects and solvent-solute interactions. In view of our interest in the thermodynamics of protonation of substituted pyridines and associated solvent effects, we have investigated the

papers, ${ }^{9,10}$ as well as to other selected literature data, we have applied the approach developed by Hepler ${ }^{5-8}$ and Bolton ${ }^{1-4}$ and their co-workers, in order to assess quantitatively the relative importance of solvation factors in the effect of substituents.

## EXPERIMENTAL

Measurements of $\mathrm{p} K_{\mathrm{a}}$.-The technique employed was the same as that already used in earlier work. ${ }^{9-11}$

## RESULTS AND DISCUSSION

Equilibrium (1) was measured as a function of temperature in the range $5-65{ }^{\circ} \mathrm{C}$. Determination of the
the first, which had been already used in previous papers, ${ }^{\mathbf{9}, 10}$ the free energy changes $\Delta G^{0}$ of reaction (1) were fitted to the thermodynamic equation (2) which

$$
\begin{equation*}
\Delta G^{0}=\Delta H_{0}^{0}+A T \ln T+I T \tag{2}
\end{equation*}
$$

represents $\Delta G^{0}$ as a function of temperature in the particular case in which the difference $\left(\Delta C_{p}\right)$ between molar heat capacities of products and reactants ( $A=$ $\left.\Delta C_{p}=\mathrm{d} \Delta H^{0} / \mathrm{d} T\right)$ may be considered constant in the temperature range investigated. The values of the constants $\Delta H_{0}{ }^{0}, A$, and $I$ were obtained by an optimization procedure and are given in Table 2.

The thermodynamic functions were also calculated by

${ }^{a}$ Experimental values (and standard deviation). ${ }^{b}$ Calculated values [thermodynamic optimization method, equation (2)]. c Values obtained by the Clarke and Glew procedure.
acid-base concentration ratio was carried out spectrophotometrically in buffered solutions at constant ionic strength $(0.02 \mathrm{M})$. The results in the form of $\mathrm{p} K_{\mathrm{a}}$ values and their standard deviations are summarized in Table 1.

For the calculation of thermodynamic functions from equilibrium data, two procedures were employed. In
${ }^{9}$ I. R. Bellobono and P. Beltrame, J. Chem. Soc. (B), 1969, 620.
the method developed by Clarke and Glew. ${ }^{12}$ Computation was carried out by the regression equation containing only three temperature-dependent variables, as the precision of the data did not allow a greater
${ }^{10}$ I. R. Bellobono and E. Diani, J.C.S. Perkin II, 1972, 1707. ${ }^{11}$ I. R. Bellobono and G. Favini, J. Chem. Soc. (B), 1971, 2034.
${ }^{12}$ E. C. W. Clarke and D. N. Glew, Trans. Faraday Soc., 1966, 62, 539.
complexity than this. The application of this procedure to acid ionization data has been thoroughly discussed. ${ }^{1-4,13}$ The recommended procedure was followed, with minor differences, such as that of calculating temperature variables by a suitable subroutine program.

By both calculation methods [use of equation (2), which we shall call hereafter the thermodynamic optimization method, and the Clarke and Glew procedure], the free energy $\left(\Delta G^{0}\right)$, enthalpy ( $\Delta H^{0}$ ), and entropy ( $\Delta S^{0}$ ) of reaction (1) could be evaluated as continuous, well-behaved functions of temperature. Their values at 298.2 K as well as those for equilibrium (1) with $\mathrm{R}=\mathrm{H}$ and $2-, 3$-, and $4-\mathrm{NO}_{2}$ are reported in Table 2. $\mathrm{p} K_{\mathrm{a}}$ Values for these latter equilibria were taken from previous measurements 9 ,10 which had previously been fitted only to equation (2).

The same type of treatment (cf. Table 2) was also applied to other literature data for the proton dissociation of monosubstituted pyridinium ions in aqueous solution which meet the requirement of having been measured over the temperature range $5-65^{\circ} \mathrm{C}$. They include ions where $\mathrm{R}=\mathrm{H},{ }^{14} 2$-, 3 -, and $4-\mathrm{Me},{ }^{14} 2$-, 3 -, and $4-\mathrm{CHO},{ }^{15} 2$-, 3 -, and $4-\mathrm{Ac},{ }^{16} 2-\mathrm{CH}_{2} \mathrm{NHMe}^{17}$ and $4-\mathrm{NH}_{2}{ }^{18}$

The free energy and the enthalpy changes for the proton dissociation of pyridinium ions are linearly correlated. The points which deviate most are those for ortho-pyridinium ions ( $2-\mathrm{Ac}, 2-\mathrm{CHO}, 2-\mathrm{CH}_{2} \mathrm{NHMe}$ ) and those for CHO and Ac groups (after excluding data for these derivatives $\Delta G_{298 \cdot 2}^{0} / \mathrm{cal}_{\mathrm{mol}}{ }^{-1}=$ $0.836 \Delta H^{0}{ }_{298 \cdot 2 \mathrm{~K}} / \mathrm{cal} \mathrm{mol}^{-1}+2453$; correlation coefficient $r=0.9881$ by the Clarke and Glew treatment; $\Delta G_{298.2 \mathrm{~K}}^{0} / \mathrm{cal} \mathrm{mol}^{-1}=0.911 \Delta H_{298 \cdot 2 \mathrm{~K}}^{0} / \mathrm{cal} \mathrm{mol}^{-1}+2274$; $r=0.9892$ by the thermodynamic optimization method).

The anomalous behaviour of CHO and Ac groups is also shown by the Hammett $\sigma$ plot and may be explained, partly at least, in terms of hydrogen bonding, since the protonated nitrogen of a pyridinium ion is one of the most electron-attracting side chains which can be visualized. ${ }^{19}$

Experimental data for unsubstituted pyridine deserve more comment. While measurements of $\mathrm{p} K_{a}$ by Perkampus and Prescher ${ }^{14}$ substantially agree with those of a previous paper ${ }^{9}$ in the range $20-30{ }^{\circ} \mathrm{C}$, a certain discrepancy arises at higher temperatures, so that the data of these authors yield for the enthalpy of reaction at $298 \cdot 2 \mathrm{~K}$ a value of $6 \cdot 41$, by the Clarke and Glew method, and $5.33 \mathrm{kcal} \mathrm{mol}^{-1}$ by the thermodynamic optimization method, as compared with 4.35 and 4.02 $\mathrm{kcal} \mathrm{mol}^{-1}$ respectively (see Table 2) obtained from the experimental data of ref. 9. The latter values are $0.45-0.78 \mathrm{kcal} \mathrm{mol}^{-1}$ below the calorimetric value; ${ }^{20}$ those derived from Perkampus and Prescher exceed it

[^0]by $1.21-0.53 \mathrm{kcal} \mathrm{mol}^{-1}$. The reason for this is not clear; it may be simply attributed to experimental uncertainties, particularly in the measurements of $\mathrm{p} K_{\mathrm{a}}$ at high temperatures. This explanation, however, is not entirely satisfactory, since in this circumstance the same scattering should be observed for all other points.
As it has been observed for a limited number of data, ${ }^{10}$ and can be assessed more clearly now for the comprehensive series of ions examined in this paper (cf. Table 2), entropy changes, associated with solvation factors, are scarcely influenced by substituents. The correlation $\Delta S^{0}{ }_{298 \cdot 2 \mathrm{~K}}$ ws. $\Delta H^{0}{ }_{2982 \mathrm{~K}}$ shown graphically in Figure $1 a$ $\left(\Delta S_{298 \cdot 2 \mathrm{~K}}^{0} / \mathrm{cal} \mathrm{mol}{ }^{-1} \mathrm{~K}^{-1}=5.63 \times 10^{-4} \quad \Delta H^{0}{ }_{298 \cdot 2} / \mathrm{Kal}\right.$ $\mathrm{mol}^{-1}-8.087 ; r=0.8133$, by the Clarke and Glew procedure) reaches the limit of acceptability only when ortho-derivatives, as well as those containing CHO and Ac groups, are excluded. The points for unsubstituted

Figure 1 Proton dissociation of substituted pyridinium ions in aqueous solution. Entropy vs. enthalpy of reaction (1) at $298 \cdot 2 \mathrm{~K}$ (numbers as in Table 2)
pyridine and for 4 -aminopyridine are the most scattered, notwithstanding the fact that the experimental data for the latter ${ }^{18}$ are to be considered among the most reliable: their exclusion leads to the better correlation of Figure $\mathrm{l} b\left(\Delta S^{0}{ }_{298 \cdot 2 \mathrm{~K}} / \mathrm{cal} \mathrm{mol}^{-1} \mathrm{~K}^{-1}=7.51 \times 10^{-4} \Delta H^{0}{ }_{298 \cdot 2} / \mathrm{K} / \mathrm{cal}\right.$ $\mathrm{mol}^{-1}-8.03 ; r=0.9678$ ). It has been shown that such isoequilibrium relationships ${ }^{21}$ derive, by thermodynamics, from the Hammett op equation and the assumption $\delta \Delta C_{p}=0$ (where $\delta$ indicates the difference between substituted and unsubstituted substrates) both of which are valid over a range of temperatures. The significance and limitations of enthalpy-entropy relationships have been critically discussed. ${ }^{22}$
In the model proposed by Hepler for substituent and solvent effects, thermodynamic functions are taken to be sums of environmental contributions (solvent-solute

[^1]interactions) and internal contributions (intrinsic to the molecules of acid and base taking part in the acid ionization). With the assumption that $\delta \Delta S^{0}{ }_{\text {int }} c a .0$ for symmetrical reactions (as a consequence: $\delta \Delta S^{0} \approx$ $\delta \Delta S^{0}{ }_{\text {env }}$ ) and that $\delta \Delta H_{\text {int }}^{0}$ is independent of temperature, this model leads to an isoequilibrium relationship, between substituent-induced changes in enthalpy ( $\delta \Delta H^{0}$ ) and entropy $\left(\delta \Delta S^{0}\right)$, of the form (3) where $\beta_{\mathrm{env}}$ is the
\[

$$
\begin{align*}
\delta \Delta H^{0} & \approx \beta_{\mathrm{env}} \delta \Delta S^{0}-[(\mathrm{l}+\gamma) /(\mathrm{d} \gamma / \mathrm{d} T)] \delta \Delta S^{0} \\
& \approx \beta_{\mathrm{env}} \delta \Delta S^{0}+(1+\gamma) \delta \Delta H_{\mathrm{int}}  \tag{3}\\
& \approx \beta_{\mathrm{env}} \delta \Delta S^{0}+\delta \Delta G^{0}
\end{align*}
$$
\]

environmental parameter,' and $\gamma$ is a parameter (' solvent parameter ') that depends on the solvent and the temperature. The evaluation of these parameters has limited the practical application of equation (3). On the other hand, it should be considered a fundamental possibility of obtaining useful information about solvent-solute interactions. Bolton and Hall ${ }^{2}$ have derived a method of calculating the environmental parameter $\beta_{\text {env }}$, based on the comparison of enthalpy changes of two reaction series, A and B , which may be assumed to be proportional [equation (4)]. Expression (5) was

$$
\begin{gather*}
\delta \Delta H_{\mathrm{A}}^{0}=\theta \delta \Delta H^{0}{ }_{\mathrm{B}}  \tag{4}\\
\delta \Delta H_{\mathrm{A}}^{0}=\theta \delta \Delta H_{\mathrm{B}}^{0}-\theta \beta_{\mathrm{env}_{\mathrm{B}}} \delta \Delta S_{\mathrm{B}}^{0_{\mathrm{B}}}+\beta_{\mathrm{env}_{\mathrm{A}}} \delta \Delta S_{\mathrm{A}}^{0} \tag{5}
\end{gather*}
$$

then obtained. By a set of experimentally measurable quantities, $\theta, \beta_{\mathrm{env}_{\mathrm{A}}}$, and $\beta_{\mathrm{env}_{\mathrm{B}}}$ could thus be evaluated.

Equation (5) was applied to the thermodynamic data (A) examined in the present paper, by using as reference system the corresponding data for anilinium ions (B), for which the value of $\beta_{\mathrm{env}_{\mathrm{B}}}$ of 413 K determined by Bolton and Hall ${ }^{2}$ was employed. The problem was thus reduced to a set of systems relating two unknown constants 0 and $\beta_{\text {env }_{A}}$. Only the thermodynamic functions of proton dissociation of $m$ - and $p$-bromo- and nitro-pyridinium ions which were common to both reaction series could be used. From the values of thermodynamic functions of Table 2 and those reported ${ }^{2}$ for $m$ - and $p$-substituted anilinium ions $\beta_{\mathrm{env}_{\mathrm{A}}}=417 \pm$ 219 K and $\theta=1.21 \pm 0.80$ were calculated, the uncertainties being given as standard deviations. Elimination of the pair of equations for $\mathrm{R}=3$ - and $4-\mathrm{NO}_{2}$, which showed the greatest scattering in $\beta_{\mathrm{env}_{\mathrm{A}}}$ and $\theta$ values, led to the values $\beta_{\mathrm{env}_{\mathrm{A}}}=351 \pm 146 \mathrm{~K}$, and $\theta=0.956=0.419$.

From the known value of environmental parameter the $\beta_{e n v} \delta \Delta S^{0}$ and $(1+\gamma) \delta \Delta H^{0}{ }_{\text {int }}$ terms were calculated by equation (3). Results are summarized in Table 3. The $(1+\gamma) \delta \Delta H^{0}{ }_{\text {int }}$ values, which equal $\delta \Delta G^{0} \quad[c f$. equation (3)], show an excellent correlation with the substituent constant $\sigma$ as shown in Figure 2. Furthermore, they agree fairly well with experimental $\delta \Delta G^{0}$ values which are reported in Table $\mathbf{3}$ for comparison. Determination of environmental ( $\delta \Delta H_{\mathrm{env}}=\beta_{\mathrm{env}} \delta \Delta S^{0}+$ $\gamma \delta \Delta H^{0}{ }_{\text {int }}$ ) and intrinsic ( $\delta \Delta H^{0}{ }_{\text {int }}$ ) enthalpy contributions is not possible without knowing the value of the solvent parameter $\gamma$. The term $\beta_{\text {env }} \delta \Delta S^{0}$ gives quantitative
information on the differential enthalpy effects brought about by substituents for the system in different states of solvation.

The good agreement of the $\beta_{\text {env }}$ value for pyridinium ions with that for anilinium ions, which are of the same
