# $X$-Ray Crystal Structure of the Electro-optic Material meta-Nitroaniline 

By Andrzej C. Skapski,* Chemical Crystallography Laboratory, Imperial College, London SW7 2AY John L. Stevenson, Department of Electrical Engineering, Imperial College, London SW7 2BT

#### Abstract

The crystal and molecular structure of the title compound has been determined from three-dimensional $X$-ray data by Patterson methods. Crystals are orthorhombic. $a=6 \cdot 501(2), b=19 \cdot 330(4)$. and $c=5 \cdot 082$ (2) A, space group $P b c 2_{1}$. and $Z=4$. Full-matrix least-squares refinement. using 541 independent reflections, has reached $R 0.084$. The molecular structure is unexceptional. with mean $\mathrm{C}-\mathrm{C} . \mathrm{C}-\mathrm{N}$. and $\mathrm{N}-\mathrm{O}$ distances of $1 \cdot 384.1 \cdot 423$. and $1.227 \AA$. The molecule is almost perfectly planar but some of the exocyclic atoms may be fractionally distorted out of the plane of the benzene ring. The packing of the molecules is quite different from that recently suggested on the basis of packing considerations. and has been shown to correlate well with the linear electro-optic properties.

meta-Nitroaniline is one of a large group of metadisubstituted benzenes crystallising in the $m m 2$ point group. ${ }^{1}$ As non-centrosymmetric solids these compounds have been investigated electrically, as piezoelectric and linear electro-optic (Pockels effect) materials. ${ }^{1,2}$ The electro-optic properties of $m$-nitroaniline are quite unusual and have generated considerable interest, since the ratios of its non-linear optical susceptibilities to the low-field linear constants are markedly anomalous. ${ }^{2}$ Previous structural determinations of $m$-dihydroxybenzene ${ }^{3}$ (resorcinol) and $m$-dinitrobenzene ${ }^{4}$ gave no real clue to the origins of this behaviour. In order to attempt a basic quantitative treatment of both the electro-optic and also the linear electrochromic effect in $m$-nitroaniline we have carried out a threedimensional $X$-ray structure analysis.

We have already given a preliminary account ${ }^{2}$ of the structure and its relation to the electro-optic behaviour. We now report the full details of the structure determination.

## EXPERIMENTAL

$m$-Nitroaniline was recrystallised from acetone as yellow orthorhombic plates.

Crystal Data.- $-\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{~N}_{2} \mathrm{O}_{2}, \quad M=138 \cdot 13$. Orthorhombic, $a=6.501(2), b=19.330(4), c=5 \cdot 082(2) \AA, U=638.6 \AA^{3}$, $D_{\mathrm{m}}=1 \cdot 42, Z=4, D_{\mathrm{c}}=1 \cdot 44, F(000)=288 . \quad \mathrm{Cu}-K_{\alpha}$ radiation, $\lambda=1.5418 \AA, \mu\left(\mathrm{Cu}-K_{\alpha}\right)=9.3 \mathrm{~cm}^{-1}$. Space group $P b c 2_{1}$ (No. 29) from systematic absences: $h 0 l, l=2 n+1$, and $0 k l, k=2 n+1$.

The crystals have $b$ perpendicular to the plate, and have hemimorphic habit. They are very susceptible to mechanical damage, with easy ( 010 ) cleavage. Accurate unit-cell dimensions were obtained by measuring some high-angle $\alpha_{1}$ and $\alpha_{2}$ reflections on a diffractometer, and they agree reasonably well with previously published values. ${ }^{5,6}$ We have retained the non-standard axial notation to facilitate comparison with previous work.

The single crystal used to collect the intensity data was ca. $0.23 \times 0.13 \times 0.05 \mathrm{~mm}$, and was mounted about the $c$ axis on a Siemens off-line four-circle diffractometer.

$\mathrm{Cu}-K_{\alpha}$ radiation at a take-off angle of $4.5^{\circ}$, a nickel $\beta$ filter, and a $\mathrm{Na}(\mathrm{Tl}) \mathrm{I}$ scintillation counter were used. The intensities of 541 independent reflections (to $\theta 60^{\circ}$ ) were measured by use of the $\theta-20$ scan technique with a ' fivevalue' measuring procedure (one side of peak, background, full peak, background on other side of peak, other side of peak). Of these, 40 were judged to be unobserved having a net count $<2 \cdot 58 \sigma$ (i.e. below the $99 \%$ confidence level). The 130 reflection was measured as a reference every 25 reflections and its net count did not vary noticeably during the data collection (ca. 2 days). Data were scaled by use of the reference reflection, and Lorentz and polarisation corrections were applied. At a later stage the data were corrected for absorption according to the methorl of Busing and Levy, ${ }^{7}$ using an $8 \times 8 \times 8$ grid with crystal pathlengths determined by the vector-analysis procedure of Coppens et al. ${ }^{8}$
Solution and Refinement of the Structure.-The major programs used to solve and refine the structure were those in the Crystal Structure Calculations System ' $X$-Ray ' 63 ' 9 and its updated version of July $1970,{ }^{10}$ although in the early stages the least-squares program NUCLS ${ }^{11}$ was also used. Calculations were performed on the Imperial College IBM 7094 and CDC 6400 and the University of London CDC 6600 computers.

Since the molecular structure was simple and probably planar we decided to attempt solution by Patterson rather than direct methods. From a three-dimensional originremoved Patterson synthesis it proved possible to predict the approximate tilt of the molecule, and by use of packing considerations to place the molecules near their true position in the unit cell. The atomic co-ordinates, however, were not sufficiently accurate and several attempts at leastsquares refinement were unsuccessful, with some atoms drifting to unacceptable positions. We therefore decided to restrain the individual movement of the atoms and to use the rigid-body refinement facility of the program NUCLS. This had the desired effect, and $R$ dropped to $0 \cdot 24$. Refinement was now transferred to the full-matrix ORFLS program, and isotropic refinement of individual atoms gave $R 0 \cdot 125 . \quad$ In this and all subsequent calculations the $z$ parameter of $\mathrm{O}(1)$ was fixed to define the arbitrary origin in this direction. When the atoms were allowed to

fixed atom contribution, with isotropic temperature factors of their parent atoms, refinement gave $R 0.086$.

Data were now corrected for absorption, and, although

The atomic scattering factors for oxygen, nitrogen, and carbon were taken from ref. 14 and for hydrogen from ref. 15. Final fractional co-ordinates of the non-hydrogen atoms and their estimated standard deviations are listed in Table 1, while Table 2 shows the coefficients in the expression for the anisotropic temperature factor $\exp \left[-\left(\beta_{11} h^{2}+\right.\right.$ $\left.\left.\beta_{22} k^{2}+\beta_{33}{ }^{2}+2 \beta_{12} h k+2 \beta_{13} h l+2 \beta_{23} k l\right)\right]$ and also the root-mean-square amplitudes of vibration along the principal axes of the thermal ellipsoid. Table 3 lists the unrefined co-ordinates of the hydrogen atoms. The observed and the calculated structure amplitudes are listed in Supplementary Publication No. SUP 20692 ( 7 pp., 1 microfiche).*

## DESCRIPTION OF THE STRUCTURF AND DISCUSSION

Figure 1 shows the molecular structure and also the thermal vibration ellipsoids ${ }^{16}$ of the non-hydrogen atoms. The more important bond lengths and bond angles are given in Table 4.

the $R$ remained virtually unchanged, slightly improved bond lengths resulted. Up to this point, in view of the nearly constant counting statistics in the data collection, ${ }^{12}$ each reflection had been assigned unit weight. A weighting scheme of the type suggested by Hughes ${ }^{13}$ was now applied, where $w=1$ for $F<F^{*}, \sqrt{ } w=F^{*} / F$ for $F \geq F^{*}$, with $F^{*}=12$ being the final optimum value. The application of a weighting scheme reduced $R$ to 0.085 , and appreciably lower standard deviations were obtained. One very strong

The structure of the molecule is as expected, essentially planar, with a mean $\mathrm{C}-\mathrm{C}$ bond length of $1.384 \AA$. This

Figure 1 The molecular structure; thermal vibration ellipsoids are scaled to enclose $50 \%$ probability
is fractionally shorter than the literature mean ${ }^{17}$ of $1.394 \AA$, but our distances have not been corrected for librational movement. The $\mathrm{C}-\mathrm{N}$ (amino) distance of

[^1]$1.406 \dagger$ and $\mathrm{C}-\mathrm{N}$ (nitro) of $1.440 \AA$ may be compared with 1.377 and $1.474 \AA$ in $p, N$-dimethyl- $m$-nitroaniline, ${ }^{18}$ 1.371 and $1.460 ~ \AA$ in $p$-nitroaniline, ${ }^{19}$ and 1.358

and $1.405 \AA$ in $N N$-dimethyl- $p$-nitroaniline. ${ }^{20}$ However, strict comparison is hindered by the likelihood of
pected show a higher degree of thermal motion than the other atoms.

The packing of the molecules is shown in Figure 2 as a stereoscopic pair ${ }^{16}$ of drawings. The arrangement of the molecules found is quite different from that recently suggested by Southgate and Hall ${ }^{6}$ on the basis of packing considerations. In their structure the molecular plane contained the $b$ axis (see Figure 1 in ref. 6), whereas we find that the least-squares plane through the molecule makes angles of $c a .59,58$, and $47^{\circ}$ with the ( 100 ), ( 010 ), and (001) planes. The arrangement of the molecules is consistent with the observed (010) cleavage. Figure 2 shows the polar nature of the $c$ axis, with all the nitrogroups pointing in the same sense. We stress that no attempt was made to determine the absolute configuration of the crystal by use of the anomalous scattering of oxygen, ${ }^{21}$ and the configuration shown in Figure 2 is therefore arbitrary.
The shorter intermolecular distances are shown in Table 5. The shortest of these ( $3 \cdot 25 \AA$ ) is between an amine nitrogen and a nitro-group oxygen atom. $\mathrm{N}-\mathrm{H} \cdot \mathrm{O}$ hydrogen bonds are normally rather shorter, e.g. $2.92-2.94 \AA$ for amino-group $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ bonds in

Figure 2 A stereoscopic view of the packing
quinonoid resonance structures in the $p$-nitroanilines, and the generally medium standard of accuracy of these structures (all have $R>0.08$ ). The average value of the $\mathrm{N}-\mathrm{O}$ distance $(1 \cdot 227 \AA)$ is very similar to the uncorrected values found in $p$-nitroaniline ${ }^{19}$ and $p, N$-di-methyl- $m$-nitroaniline. ${ }^{18}$ The oxygen atoms as ex-

[^2]two adenine complexes, ${ }^{22,23}$ or 3.07 and $3 \cdot 14 \AA$ in $p$ nitroaniline. ${ }^{19}$ At best, therefore, this distance may represent a very weak interaction. The perpendicular distance between the planes of $m$-nitroaniline molecules stacked in the $c$ direction is $c a .3 \cdot 5 \AA$.

When a least-squares plane was calculated through all ten non-hydrogen atoms of the molecule it was found that the maximum deviation was $0.03 \AA$. However, when the calculation was repeated with only the six carbon atoms defining the plane the planarity was now very much better $(+0.011$ to $-0.012 \AA)$, and it does seem likely that at least some of the nitrogen and oxygen atoms are slightly distorted from this plane.

The implications of this structure to the linear electrooptic and linear electrochromic effects have been discussed, ,24 and it has been shown that the use of a simple theoretical model, in which $m$-nitroaniline is treated as a molecular solid, gives good correlation between the structure and these properties.

We thank Dr. S. R. Fletcher for assistance in collecting the diffractometer data and for adaptations to the rigidbody refinement program used in the early stages of solution of the structure, Dr. E. A. D. White for discussions, Professor D. Rogers for use of the Siemens diffractometer, and the Post Office for a Postgraduate Award (to J. L. S.).
