## Crystal Structure of $6 \beta$-Trimethylammoniopenicillanate Hemihydriodide $\dagger$

By Philip J. Cox,* Richard J. McClure, and George A. Sim,* School of Molecular Sciences, University of Sussex, and Chemistry Department, University of Glasgow, Glasgow G12 800

Crystals of the title compound are monoclinic, space group $C 2$, with $a=19 \cdot 44(3), b=6 \cdot 28(1), c=11 \cdot 33(2) A$, $\beta=95.0(1)^{\circ}, Z=4$. The atomic co-ordinates were obtained from $X$-ray measurements by Fourier and leastsquares calculations, the final value of $R$ being $9 \cdot 0 \%$ for 1380 visually estimated reflections. The carboxylate groups of two penicillanate groups are related by a short $O(13) \cdots O\left(13^{\mathrm{I}}\right)$ separation of $2 \cdot 46(2) \AA$ across a two-fold axis; this distance is typical of the short hydrogen-bonded separations in the acid salts of some carboxylic acids and the heminydriodide is therefore formulated as $\left[\mathrm{RCO}_{2} \cdots \mathrm{H} \cdots \mathrm{O}_{2} \mathrm{CR}\right]+1-$. The $\beta$-lactam ring is puckered, with $C(7)$ displaced by $0.31 \AA$ from the plane defined by atoms $C(5), N(4)$, and $C(6)$. The thiazolidine ring approximates closely to an envelope form, with $\mathrm{C}(3)$ displaced by $0.47 \AA$ from the mean plane through atoms $C(2), S, C(5)$, and $N(4)$.

THE betaine $6 \beta$-trimethylammoniopenicillanate ( $\mathbf{1}$ ) forms a highly crystalline hemihydriodide ( $\left.\mathrm{C}_{11} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{O}_{3} \mathrm{~S}\right)$ $\frac{1}{2} \mathrm{HI} .{ }^{1}$ This material may be formulated as $\left(\mathrm{R}^{+} \mathrm{CO}_{2} \mathrm{H}\right.$, $\left.{ }^{-} \mathrm{O}_{2} \mathrm{CR}^{+}\right) \mathrm{I}^{-}$with a combination of carboxy-group and carboxylate anion which is well known in the acid salts
of monobasic and dibasic carboxylic acids, where it can give rise to a short symmetrical $\mathrm{O} \cdots \mathrm{H} \cdots \mathrm{O}$ hydrogen

bond. ${ }^{2}$ We undertook an $X$-ray analysis of the crystal structure of the hemihydriodide to determine whether this provides another example of such a short hydrogen

(1)
bond and, in addition, to obtain structural parameters pertinent to the correlation of molecular geometry and biological activity in penicillin and cephalosporin antibiotics. ${ }^{3}$

The crystal structure of the hemihydriodide was elucidated from a three-dimensional Fourier synthesis based on the phases of the iodine atom. The atomic coordinates were adjusted by least-squares calculations and at the end of the analysis $R$ was $9 \cdot 0 \%$ over 1380 independent structure amplitudes. The molecular structure of the penicillin derivative is shown in Figure 1 and the crystal structure is illustrated in Figure 2. The

Figure 1 A general view of the molecular structure

Figure 2 The crystal structure viewed in projection along the $b$ axis; the positive direction of the $b$ axis projects into the page
atomic co-ordinates and thermal parameters are given in Table 1, while Tables 2-6 list the bond lengths, valency

[^0]angles, torsion angles, displacements from mean planes, and intermolecular separations.

axis then we have an example of a symmetrical $\mathrm{O} \cdots \mathrm{H}$ $\cdots \mathrm{O}$ hydrogen bond. On the other hand, if the proton is randomly disordered over two alternative sites on either side of the two-fold axis then the hydrogen bond would be of the normal unsymmetrical $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ type. The $\mathrm{O} \cdots \mathrm{O}$ interaction at $2 \cdot 46 \AA$ may be compared with a number of ' very short ' hydrogen bonds ${ }^{2}$ found in acid salts of carboxylic acids: for example, intermolecular hydrogen bonds involving crystallographic two-fold symmetry occur in sodium hydrogen diacetate $[2 \cdot 44(1) \AA],{ }^{4}$ potassium hydrogen succinate $[2 \cdot 446(4) \AA],{ }^{5}$ ammonium hydrogen glutarate $[2 \cdot 406(7) \AA]^{6}$ and potas-

[^1]sium hydrogen acetylenedicarboxylate $[\mathbf{2} \mathbf{4 4 5 ( 3 )} \AA] .^{7}$ In the case of the acid salts there is strong evidence that ' very short' hydrogen bonds which lie across crystallographic elements of symmetry are genuinely symmetrical, ${ }^{2}$ and this may also be true for the hydrogen bond in the hemihydriodide.

The bond lengths in the carboxy-group show that $\mathrm{C}(11)-\mathrm{O}(12)(\mathrm{l} \cdot 23 \AA)$ has more double-bond character

Table 6

$O(13) \cdots C\left(17^{1 \mathrm{~V}}\right) \quad 3 \cdot 32$
Roman numerals as superscripts refer to the following transformations of the atomic co-ordinates:

$$
\begin{aligned}
& \text { I }-x, y, 1-z \\
& \text { II } x, 1+y, z \\
& \text { III } x,-1+y, z \\
& \text { IV }-\frac{1}{2}+x,-\frac{1}{2}+y, z
\end{aligned}
$$

$$
\begin{gathered}
\text { V } \frac{1}{2}-x, \frac{1}{2}+y,-z \\
\text { VI } \frac{1}{2}-x, \frac{1}{2}+y, 1-z \\
\text { VII } \frac{1}{2}-x,-\frac{1}{2}+y,-z
\end{gathered}
$$

$$
\begin{array}{ll}
\text { IV }-\frac{1}{2}+x,-\frac{1}{2}+y, z & \text { VIII } \frac{1}{2}-x, x,-\frac{1}{2}+y,-z \\
\frac{1}{2}-1-z-z
\end{array}
$$

than $\mathrm{C}(11)-\mathrm{O}(\mathbf{1 3})(1 \cdot 30 \AA)$, whereas in an unperturbed carboxylate anion both bonds are normally of the same length, $c f$. distances of 1.240 and $1.245 \AA$ in the zwitterionic form of ampicillin trihydrate. ${ }^{8}$

The $\beta$-lactam ring in the hemihydriodide displays a buckled conformation, with atom C(7) displaced $0.31 \AA$ above the plane defined by atoms $\mathrm{C}(5), \mathrm{N}(4)$, and $\mathrm{C}(\mathbf{6})$. In phenoxymethylpenicillin ${ }^{9}$ and potassium benzylpenicillin ${ }^{10}$ atom $\mathrm{C}(7)$ of the $\beta$-lactam is displaced by $0 \cdot 15 \AA$. The thiazolidine ring has an envelope conformation in which $\mathrm{C}(3)$ is $0.47 \AA$ out of the plane containing atoms $\mathrm{S}(1), \mathrm{C}(2), \mathrm{N}(4)$, and $\mathrm{C}(5)$. In phenoxymethylpenicillin the corresponding displacement is $0.51 \AA \AA^{9}$

The lactam nitrogen atom is displaced by $0.29 \AA$ from the plane of its three substituents $\mathrm{C}(3), \mathrm{C}(5)$, and $\mathrm{C}(7)$. In benzylpenicillin the displacement is $0 \cdot 40 \AA$. Dahl has observed that the $\beta$-lactam nitrogen atom has a greater pyramidal character in active $\Delta^{3}$-cephalosporin antibiotics than in the inactive $\Delta^{2}$-cephalosporin, being displaced by $c a .0 \cdot 2-0.3 \AA$ from the plane of its three substituent atoms in the former case and by only $0.06 \AA$ in the latter, and that the departure from coplanarity can be correlated with the ease of base hydrolysis of the $\beta$-lactam amide bond. ${ }^{3}$

$95.0(1)^{\circ}, \quad U=1377 \AA^{3}, \quad D_{\mathrm{m}}=1.55, \quad Z=4, \quad D_{\mathrm{c}}=1.56$, $F(000)=660$. Space group C2 $\left(C_{2}^{3}\right) . \quad$ Mo- $K_{\alpha}$ radiation, $\lambda=0.7107 \AA ; \mu\left(\mathrm{Mo}-K_{\alpha}\right)=13.7 \mathrm{~cm}^{-1}$.

Crystallographic Measurements.-Rotation, Weissenberg, and precession photographs were taken. The systematically absent reflections for the optically active compound indicated the space group C2. Intensity data were obtained from layers $h 0-6 l$ of equi-inclination Weissenberg photographs taken with Zr -filtered $\mathrm{Mo}-K_{\alpha}$ radiation. A JoyceLoebl integrating microdensitometer was used to measure the intensities, which after correction for Lorentz and polarization effects gave 1380 independent structure amplitudes. The various layers were placed on a common scale by correlation with a limited set of intensities obtained from precession photographs.

Structure Analysis.-The iodine atom, which lies on a two-fold symmetry axis, was used to define the origin of the cell, and the co-ordinates of the sulphur atom were found from a Fourier synthesis. A subsequent Fourier synthesis based on the phases of the iodine and sulphur atoms showed little pseudo-symmetry and fourteen further atoms were unambiguously located. After two cycles of least-squares calculations with isotropic thermal parameters $R$ was $24 \cdot 1 \%$ and a Fourier difference synthesis gave the co-ordinates of

* Sce Notice to Authors No. 7 in J.C.S. Dalton, 1972, Index issue.
the two remaining carbon atoms. A further two cycles of isotropic refinement lowered $R$ to $15 \cdot 1 \%$.
The iodine and sulphur atoms were next assigned anisotropic temperature factors and one cycle of least-squares calculations gave $R \mathbf{9 . 5 \%}$. Corrections for anomalous dispersion were applied to the iodine scattering factor ${ }^{11}$ and two further rounds of calculations reached convergence at $R \mathbf{9 . 0 \%}$. A final difference electron-density distribution gave no clear indication of hydrogen atom positions. A unitary weighting scheme ( $w=1$ ) was retained throughout the least-squares calculations as $\left\langle w \Delta^{2}\right\rangle$ was approximately constant over various ranges of $\left|F_{0}\right|$ and $\sin \theta$. Observed and calculated structure amplitudes are listed in Supplementary Publication No. SUP 20911 ( 9 pp ., 1 microfiche).*

The various calculations were performed on an Atlas computer at the S.R.C. Chilton Laboratory, an ICL 1905 computer at the University of Sussex, and a KDF 9 computer at the University of Glasgow. We thank the S.R.C. for the purchase of the microdensitometer, the U.S. National Institutes of Health for a fellowship (to R. J. McC.), and Dr. J. H. C. Naylor (Beecham Research Laboratories) for a supply of the hemihydriodide.
