## Conformation of 1-(2-Bromophenyl)azetidin-2-one and 1-(2-Bromo-phenyl)pyrrolidin-2-one

## By Hideji Fujiwara, Rodney L. Varley, and James M. van der Veen,* Department of Chemistry and

 Chemical Engineering, Stevens Institute of Technology, Hoboken, New Jersey 07030, U.S.A.
#### Abstract

U.v. data suggest that 1-(2-bromophenyl)pyrrolidin-2-one (2a) is substantially non-planar in solution while the related 1-(2-bromophenyl)azetidin-2-one (1a) is planar. Crystal structure studies of these two compounds show this effect exists in the solid also and that there is a $72^{\circ}$ dihedral angle between normals to the phenyl and fivemembered rings in the $\gamma$-lactam (2a), while the rings in the $\beta$-lactam (1a) are coplanar. Compound (1a) crystallizes in space group $C 2 / c$ with cell dimensions $a=15.91(1), b=7.70(1), c=14.48(1) ~ A, \beta=103.84(1)^{\circ}$ while compound (2a) crystallizes in space group $P 2_{1} / c$ with $a=10.55(1), b=6.83(1), c=15.41(1) ~ \AA, \beta=$ $112.02^{\circ}(2)$. Both structures were solved by heavy atom methods.

U.v. and n.m.r. spectra of $\beta$ - and $\gamma-N$-phenyl-lactams in solution suggest that the intensity of the absorption band at $c a .250 \mathrm{~nm}$ can be used as an indication of the coplanarity of the $N$-phenyl substituent and the heterocyclic
penicillin and cephalosporin antibiotics. Table 1 shows u.v. data for lactams (1) and (2). ${ }^{1}$ Manhas et al. interpreted these spectra as indicating that there is a substantial dihedral angle between the $N$-phenyl sub-

four- or five-membered ring. $\beta$-Lactams are of particular interest because they are part of the ring system in

Table 1
U.v. spectra of $\beta$ - and $\gamma$ - ( $o$ - and $p$-bromophenyl)-lactams

| Compound | $\lambda_{\text {max. }} / \mathrm{nm}$ | $\varepsilon$ |

stituent and the $\gamma$-lactam ring in (2a) (i.e. the angle between normals to the two rings) while in the $\beta$-lactam (la) the corresponding dihedral angle was very small. This would interfere with resonance interaction in the $\gamma$-lactam resulting in a wavelength shift from 247 nm to weak multiple bands at 267,273 , and 293 nm with a substantial diminution of the extinction coefficient. There is some effect on the extinction coefficient in the
${ }^{1}$ M. S. Manhas, S. Jeng, and A. K. Bose, Tetrahedron, 1968, 24, 1237.
$\beta$-lactam (la) but no comparable change in the absorption wave length.

In order to test these hypotheses we have solved the crystal structures of 1-(2-bromophenyl)azetidin-2-one (la) and 1-(2-bromophenyl)pyrrolidin-2-one (2a). The reported crystal structures of $N$-phenyl-substituted $\beta$ lactams contain halogen in the para-position ${ }^{2,3}$ and do not show the striking u.v. effects seen in the ortho-substituted phenyl compounds (la) and (2a). There are no reports of $\gamma$ - N -aryl-lactams although the related structure $N$-4-bromophenylsuccinimide $(3)^{4}$ shows a $65^{\circ}$ dihedral angle between the plane of the phenyl group and five-membered ring. This angle has been ascribed to steric interaction between the orthohydrogens and the carbonyl oxygen atoms.

## EXPERIMENTAL

Compound (la) was prepared by established methods from $o$-bromoaniline and $\beta$-bromopropionic acid. ${ }^{5}$ Recrystallization from hexane yielded needle-like crystals elongated
the crystals in a thin-walled glass capillary as significant sublimation occurred over the period used for data collection. Multiple film Weissenberg techniques were used to collect the data with intensities estimated by visual comparison with a calibration strip. The data was then merged with the computer program of Hamilton et al. ${ }^{6}$ Of 1240 reflections collected within the $\mathrm{Cu}-K_{\alpha}$ sphere, 993 were considered observed. All calculations were performed on the PDP-10 computer using Stewart's $X$-ray- 72 computer programs. ${ }^{7}$
The data was placed on an absolute scale by Wilson's method, ${ }^{8}$ and the bromine located in a Patterson map. All non-hydrogen atoms were evident on the first Fourier map phased on bromine alone. After block diagonal isotropic refinement the agreement factor $R$ was 0.17 . Three cycles of anisotropic full matrix refinement with Hughes ${ }^{9}$ weighting scheme reduced the weighted $R$ to 0.097 . Inclusion of calculated hydrogen positions at a C-H distance of $1.0 \AA$ and two full matrix least square cycles (isotropic hydrogen and anisotropic $\mathrm{C}, \mathrm{N}, \mathrm{O}, \mathrm{Br}$ ) gave a final weighted $R$ of 0.088 . The largest shift : error ratio by this time was 0.5 . The

collected along the $b$ axis with intensities estimated by comparison with a calibration strip. Data was merged for each layer ${ }^{6}$ and then put on an approximate scale for each of four layers by means of a Wilson plot. The initial layer
while the structure factor Table 6 is available in SUP 21920. Bond distances and angles as shown in Table 7 using the numbering system shown in Figure 2.

Figure 1 Numbering system, conformation, and thermal ellipsoids for the $\beta$-lactam (la)

## DISCUSSION

The bond lengths and angles are normal in the two molecules except for some distortion in the $\beta$-lactam ring similar to that observed in related compounds. ${ }^{10}$ The $\beta$-lactam ring is planar ( $X^{2}=0.25$ ) with $\mathrm{N}(1) 0.003 \AA$

Table 5

Thermal parameters are expressed in the form $T=\exp \left[-2 \pi^{2}\left(U_{11} h^{2} a^{* 2}+U_{22} k^{2} b^{* 2}+U_{33} l^{2} c^{* 2}+2 U_{12} h k a^{*} b^{*}+2 U_{13} h l a^{*} c^{*}+\right.\right.$ $\left.\left.2 U_{23}{ }^{3} l b^{*} c^{*}\right)\right]$.
$\dagger$ No standard deviation is reported for $U_{22}$ as the data were only collected along the $b$ axis.
scale factors were refined separately once the structure had been solved. Of 1084 measured reflections 886 were considered observed. The bromine atom was located in a Patterson map and the rest of the structure was apparent in the first Fourier map phased on bromine. Anisotropic full matrix refinement of the non-hydrogen atom positions reduced $R$ to 0.108 using a Hughes weighting scheme. Positonal and thermal parameters are shown in Table 5

[^1]from the mean plane of its substituents. In biologically active lactam structures the amide nitrogen is $c a .0 .4 \AA$ from the plane of its substituents. ${ }^{10}$ It has been proposed that this non-planarity is partly responsible for the $\beta$-lactam's physiological effect. The $\beta$-lactam ring in (1a) forms a dihedral angle of $2.2^{\circ}$ with the attached $N$-phenyl aromatic ring with the carbonyl group pointed away from the direction of $\mathrm{C}-\mathrm{Br}$ bond. In addition there is a close interaction of $2.20 \AA$ between the hydrogens attached to $C(5)$ and $O(1)$. The dihedral angle in
xylene solution of (1a) is $53^{\circ}$ as determined by dipole moment measurements and quantum chemical calculations. ${ }^{11}$ The difference between this dipole moment study in xylene solution and the previous n.m.r. study in $\mathrm{CDCl}_{3}$ which suggested (la) should be planar is not explained. The $X$-ray results are in agreement with the n.m.r. solution work. Perhaps the discrepancy lies in

assumptions made in the dipole moment study. There are no intermolecular contacts less than the sum of van der Waals radii which could explain a different conformation in the solid from that in solution. There are rather close intramolecular contacts of $3.13,3.06,2.86$, and 2.28 $\AA$ for the $\mathrm{Br}(1) \cdots \mathrm{C}(7), \mathrm{Br}(\mathbf{1}) \cdots \mathrm{H}(5), \mathrm{Br}(\mathbf{1}) \cdots \mathrm{H}(\mathbf{6})$, and $\mathrm{O}(1) \cdots \mathrm{H}(4)$ bonds respectively. $[\mathrm{H}(4)$ is attached to $C(5)$ while $H(5)$ and $H(6)$ are attached to $C(7)]$.

The five-membered ring $\beta$-lactam (2a) is puckered
with $C(8)$ out of the plane of the other four atoms. The aromatic ring forms a dihedral angle of $72^{\circ}$ with the plane of lactam ring with the $\mathrm{C}-\mathrm{Br}$ bond turned toward the carbonyl group. Thus the suggestion that the u.v. spectrum of N -(o-bromophenyl)-lactams in solution is due to a non-planar conformation is confirmed in the

Figure 2 Numbering system and conformation of the $\gamma$-lactam (2a)
solid. Qualitatively the spectral effects in (2a) are substantially different from the simple diminution in extinction seen in (la) (Table 1).

We thank Mr. R. Ohanian for assistance in the initial work on the $\beta$-lactam.
