# Homoallylic Coupling in 1,4-Dihydronaphthalenes. Part 2. ${ }^{1}$ Crystal Structure of cis-2a,5-Dihydro-5-acenaphthoic Acid 

By Anthony K. Cheetham * and John M. Newsam, Chemical Crystallography Laboratory, Hooke Building, 9 Parks Road, Oxford OX1 3PD
Martin C. Grossel ${ }^{\bullet}$ and Rodney C. Hayward, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 30Y

The structure of the title compound (1) has been determined by direct methods from single-crystal $X$-ray diffractometer data. Crystals are triclinic, space group $P \overline{1}$, with $Z=2$, in a cell with lattice parameters $a=8.446(4), b=8.534(4)$, $c=8.940(3) \AA, \alpha=122.95(4)^{\circ}, \beta=107.48(3)^{\circ}$, and $\gamma=70.32(3)^{\circ}$. 2534 independent reflections gave a final $R$ of 0.057 . The dihydronaphthalene ring adopts a highly puckered boat conformation. Good agreement is found between interproton couplings predicted from the crystallographic structure and the experimental values.

From a recent detailed study ${ }^{1}$ of the n.m.r. spectrum of cis-2a,5-dihydro-5-acenaphthoic acid (1) it was concluded that in this compound the 1,4-dihydronaphthalene ring is held in a rigid and highly puckered boat conformation. A value of $\alpha, \dagger$ the angle of fold, of between 140 and $150^{\circ}$ was suggested from the measured vicinal, allylic, and homoallylic couplings about the dihydrobenzene ring. However, it was not clear from the spectral data whether this ring was symmetrically puckered, or if there was twisting about the olefinic bond. In order to confirm our predictions and to establish the actual dihedral angles between the various interacting protons, information which would allow a direct comparison of the experimental and calculated ${ }^{2,3}$ coupling constants, we have now determined the crystal structure of this compound.

[^0]The structures of several 1,4-dihydrobenzenes and analogous systems have previously been determined by $X$-ray crystallography. Cyclohexa-1,4-dienylglycine (2) ${ }^{4}$ and anti-1 ,2,4,5-tetraphenyl-3,6-dimethoxycarbonyl-cyclohexa-1,4-diene (3) ${ }^{5}$ have both been shown to contain a planar cyclohexadiene ring, in agreement with n.m.r. studies of several 1,4 -dihydrobenzoic acids. ${ }^{6}$ However, these results need not reflect an inherent conformational preference since crystal lattice forces may dominate here. Indeed, whilst 9,10 -dihydroanthracene is puckered, 9,10 -dihydro-1,2,5,6-dibenzanthracene adopts a planar conformation in the crystal. ${ }^{7}$ $4^{\prime}$-Bromo-trans-1,4-dihydro-4-tritylbiphenyl (4a) has $\alpha$ $165^{\circ}{ }^{8}$ The n.m.r. spectrum of the related compound (4b) also suggests a puckered cyclohexadiene ring (it is unlikely that variation of the substituent X should have

[^1]a significant effect on the conformation here). However, the observation ${ }^{9}$ that vicinal and allylic couplings are not identical in the cis- and trans-isomers of (4b) suggests that the conformations of these may not be

(1)

(3)

(2)

(4) $a_{:} X=B r$
$$
\text { b; } X=H
$$
identical, making comparison of crystallographic and n.m.r. data difficult.

The present study is the first in which a 1,4 -dihydrobenzene or 1,4 -dihydronaphthalene ring is held in a rigid conformation * thus removing any ambiguities in the comparison of its solid-state structure and its spectroscopic properties.

## EXPERIMENTAL

cis-2a,5-Dihydro-5-acenaphthoic acid was prepared as previously described ${ }^{1}$ and crystallised from acetonitrile.

observed and calculated structure factors, and anisotropic thermal parameters for carbon and oxygen, are listed in Supplementary Publication No. SUP 21962 ( 23 pp., 1 microfiche).*

## DISCUSSION

The structure of (1) is shown in Figures 1 and 2. There is remarkably little twisting about the double bond despite the considerable strain present in models of this compound. The actual ring-puckering angle $\alpha$ is

Figure 1 cis-2a,5-Dihydroacenaphthoic acid (1): a general view
found to be $146.5^{\circ}$, in very close agreement with the previous estimate. ${ }^{1}$ The $\mathrm{C}(2 \mathrm{a})-\mathrm{H}$ and $\mathrm{C}(5)-\mathrm{H}$ bonds are nearly parallel, a situation predicted ${ }^{6}$ to be the most favourable for homoallylic coupling. A projection along the $\mathrm{C}(5)-\mathrm{C}(4)$ bond reveals that the $\mathrm{C}(5)-\mathrm{H}$ bond has a dihedral angle of $90^{\circ}\left(\phi_{3,5}\right)$ with respect to the carbon-carbon double bond $\mathrm{C}(3)-\mathrm{C}(4)$, and of $83^{\circ}\left(\theta_{4,5}\right)$ with respect to the $\mathrm{C}(4)-\mathrm{H}$ bond where $\theta$ defines the dihedral angle between vicinal $\mathrm{C}-\mathrm{H}$ bonds and $\phi$ is used to relate the protons $\mathrm{H}-2 \mathrm{a}$ and $\mathrm{H}-5$ to the $\pi$-bond. This latter parameter was used by Barfield and co-workers ${ }^{2,3}$ when calculating allylic and homoallylic coupling constants. From a projection along $\mathrm{C}(2 \mathrm{a})-\mathrm{C}(3)$ the corresponding angles are found to have values of $82^{\circ}$ ( $\phi_{2^{a, 4}}$ ) and $105^{\circ}\left(\theta_{2^{a, 3}}\right)$.

Vicinal coupling between a methylene and a vinylic proton (e.g. $J_{2 a, 3}$ and $J_{4.5}$ ) varies as $\cos ^{2} \theta^{14-16}$ having a minimum value of $c a .1 .8 \mathrm{~Hz}$. The values of $J_{2 a, 3}$ and $J_{4.5}$ observed in the n.m.r. spectrum of (1) are

* See Notice to Authors No. 7 in J.C.S. Perkin II, 1976, Index issue.
${ }^{13}$ D. T. Cromer and J. B. Mann, Los Alamos Scientific Laboratory Report LA 3816, 1967.
${ }_{14}$ S. Sternhell, Quart. Rev., 1969, 23, 236, and references therein.
very close to this minimum, but allowance must be made for substituent effects. Using the foregoing values of $\phi$, allylic couplings of $J_{2 \mathrm{a}, 4}-3.29$ and $J_{3,5}$ -3.20 Hz are predicted from INDO calculations, ${ }^{3}$ results which agree very well with the experimental observations ( -3.22 and -3.09 Hz respectively). The structure of the five-membered ring agrees well with previous observations. ${ }^{1}$ For example, the dihedral angle $\theta_{1^{\prime}, 2}$ of $92^{\circ}$ leads to negligible coupling between H-1 ${ }^{\prime}$ and H-2. $\theta_{1,2}$ and $\theta_{1^{\prime}, 2^{\prime}}$ are both ca. $31^{\circ}$; accordingly $J_{1,2}$ and $J_{1^{\prime}, 2^{\prime}}$ are of similar magnitude.

In cis-3a,6-dihydroindane-6-carboxylic acid (5) a homoallylic coupling of 11.4 Hz is observed. ${ }^{1}$ In view of

Figure 2 Compound (1): carbon skeleton, showing the angle of fold of the dihydronaphthalene ring
the similar substitution pattern about the dihydrobenzene ring in both ( $\mathbf{1}$ ) and (5) it is not unreasonable to expect the value of $\alpha$ to be similar for these two structures (though there will be a slight effect arising from the change in length of the aromatised double bond and in the hybridisation at $\mathrm{C}-1$ ). If it is assumed that each interaction pathway in (5) is identical, then a coupling constant of ca. 5.7 Hz should be observed through the isolated double bond of (l), thus leaving a value of 2.7 Hz for that through the aromatic ring

(5)

(7)

(6)

(8)
here. This agrees quite well with the value of 4.8 Hz estimated ${ }^{6}$ for homoallylic coupling between pseudoaxial protons in 9,10-dihydroanthracene (6), where there are two aromatic interaction pathways; both n.m.r. spectroscopic ${ }^{6}$ and $X$-ray crystallographic studies ${ }^{17}$ of (6) suggest that it adopts a highly puckered

[^4]boat conformation with $\alpha c a .145^{\circ}$. For dihedral angles $\phi$ of 90 and $83^{\circ}$ between the double bond and H-2a and H-5 respectively, a homoallylic coupling constant of 5.1 Hz is predicted from the semi-empirical calculations of Barfield and Sternhell. ${ }^{2}$ This is slightly lower than the value estimated for coupling through the double bond in (1). Indeed, whilst the calculated maximum for homoallylic coupling is $10.5 \mathrm{~Hz},{ }^{6}$ values of 12.0 Hz have been observed in (7) ${ }^{18}$ and (8). ${ }^{19}$ The considerably

reduced magnitude of homobenzylic coupling [ca. 2.5 Hz in (1) and (6)] has been noted elsewhere in orthodisubstituted aromatic systems ${ }^{20}$ and presumably reflects reduced $\pi$-electron bond order in aromatic systems.
