# Basicity of Nitrogen-Sulphur(vi) Compounds. Part 3.1 Protonation Equilibria of Sulphamates using Potentiometric and ${ }^{13} \mathrm{C}$ Nuclear Magnetic Resonance Methods 

By William J. Spillane," Thomas J. Hannigan, and Kevin P. Shelly, Chemistry Department, University College, Galway, Ireland

#### Abstract

Potentiometric and ${ }^{13} \mathrm{C}$ n.m.r. methods have been used to study the sulphamate equilibria in Scheme 1. $\mathrm{p} K_{\mathrm{a}}$ Values for step b have been determined for 19 sulphamates including seven hetero-sulphamates which contain an additional nitrogen atom. The determination of $\mathrm{p} K_{1}$ (for the hetero-nitrogen atom) and $\mathrm{p} K_{2}$ (for the sulphamate nitrogen atom) required the use of a computer program in a few instances where the basicities of the two nitrogens were close (overlapping $\mathrm{p} K_{\mathrm{a}}$ values). $\mathrm{p} K_{\mathrm{a}}$ Values (ca. 12) for step a have been determined for five compounds. Step chas been studied in $\mathrm{H}_{2} \mathrm{SO}_{4}$ and the $\mathrm{p} K_{\mathrm{a}}$ values ( -1.2 to -1.74 from the Bunnett and Olsen equation) have been determined for three compounds.

In previous papers ${ }^{1,2}$ we examined the equilibrium represented as b in Scheme $\mathbf{l}$ for some aliphatic, alicyclic, alkylaryl-, and aryl-sulphamates. In this paper $\mathrm{p} K_{\mathrm{a}}$ values for equilibrium b have been determined for 19 additional sulphamates including seven hetero-sulpham-

Scheme 1
ates containing an extra nitrogen site. For some of the hetero-sulphamates the calculation of $\mathrm{p} K_{2}$ (for the sulphamate nitrogen atom) and $\mathrm{p} K_{1}$ (for the heteronitrogen atom) has been possible by the use of standard equations ${ }^{3}$ since the basicities of the two nitrogens are
separated by at least six $\mathrm{p} K$ units. Three heterosulphamates had $\mathrm{p} K_{1}$ and $\mathrm{p} K_{2}$ overlapping and a computer program was used to calculate the $\mathrm{p} K_{\mathrm{a}}$ values. ${ }^{4}$
The equilibrium a has been examined for some alkyl and alicyclic sulphamates and equilibrium c for some alkyl- and hetero-sulphamates.

Potentiometric and ${ }^{13} \mathrm{C}$ n.m.r. methods have been used to determine ionization data.

## EXPERIMENTAL

Materials.-Sulphamic acid (B.D.H.; analytical grade), cyclohexylsulphamic acid (Fluka), and sodium cyclohexylsulphamate (Fluka) were used as obtained. Sodium sulphamate was prepared from the free acid using standard sodium hydroxide. The material obtained gave a satisfactory N, H, and S analysis. Other sulphamates were synthesised as their sodium salts (unless otherwise stated in the Tables) either by the method of Audrieth and Sveda ${ }^{5}$ or by that of Boyland et al. ${ }^{6}$ by sulphamation of the appropriate commercially available amines. Yields varied from 2 to $30 \%$ (based on the amines used). $N$-Methylcycloheptylamine was prepared in $\mathbf{5 6} \%$ yield from cycloheptylamine and dimethyl sulphate ${ }^{7}$ and the amine was subsequently sulphamated.

All the sulphamates prepared gave a satisfactory ( $\pm \mathbf{0 . 5 \%}$ ) $\mathrm{C}, \mathrm{H}$, and N analysis except sodium 3-dimethylaminopropylsulphamate. I.r. spectra of all the sulphamates prepared were recorded as Nujol mulls on a Perkin-Elmer 377 spectrophotometer. All the sulphamates gave characteristic bands 8,8 at $3400-3190$ (NH), $1240-1210$ (asym- $\mathrm{SO}_{3}$ ), $1203-1170$ (sym- $\mathrm{SO}_{3}$ ), $1072-1040$ (sym$\mathrm{SO}_{3}$ ), and $730-660 \mathrm{~cm}^{-1}(\mathrm{NS})$. All the sulphamates gave a positive ' sulphamate ' test. ${ }^{10}$

Hydrochloric and sulphuric acid and sodium hydroxide solutions were prepared from Volucon ( M and B ) standards. Deuteriated sulphuric acid (99\% D) (Ryvan Chem. Co.) and
deuterium oxide (Prochem) were used as obtained. Buffered solutions for $\mathrm{pH} 4,7$, and 9.2 were prepared from buffer tablets (B.D.H.).

Potentiometric Measurements.-A Pye-Unicam model 290 MK 2 pH meter standardized with a $1 \%(\mathrm{w} / \mathrm{w})$ aqueous solution of sulphamic acid ( $\mathrm{pH} 1.18^{11}$ ) and buffers of pH 4.0 , 7.0 , and 9.2 were used. The following procedures were used for potentiometric titrations.

Method $A .^{12}$ The following procedure was typical. Compound (2) ( 0.0805 g ) was dissolved in distilled water $(47.5 \mathrm{ml}) *$ in a 100 ml . titration flask which was placed in a water-bath maintained at $25^{\circ} \mathrm{C} . \dagger$ A magnetic stirring pellet and a glass electrode were placed in the flask. After recording the initial $\mathrm{pH}, 0.1 \mathrm{~m}-\mathrm{HCl}(5 \mathrm{ml}) \ddagger$ was added in 0.5 ml portions from a 10 ml microburette. After each addition of titrant the stirrer was started for $c a .20 \mathrm{~s}$, then stopped and the pH was recorded. The concentration of (2) was such that at half-neutralization it corresponds to a 0.01 m solution. In the calculation of the $\mathrm{p} K_{\mathrm{a}}$ values allowance was made for varying hydrogen ion concentrations. A correction for the dilution of the substrate was also applied.

Method B. This was analogous to Method A except that an amount of the appropriate compound was dissolved in distilled water ( 23.75 ml ) such that at half-neutralization the concentration of the sulphamate solution was 0.01 m . In the titration $0.1 \mathrm{~m}-\mathrm{HCl}(2.5 \mathrm{ml})$ was added in 0.25 ml portions.

Method C. In this method a quantity of the compound was dissolved in distilled water ( 45 ml ) such that at halfneutralization the concentration of the sulphamate solution was 0.01 m . $\quad 0.1 \mathrm{M}-\mathrm{HCl}(10 \mathrm{ml})$ was added in 0.2 ml portions for the titration.

Method D. A quantity of the compound was dissolved in distilled water ( 22.5 ml ) such that at half-neutralization the concentration of the sulphamate was $0.01 \mathrm{~m} . \quad 0.1 \mathrm{~m}-\mathrm{HCl}$ ( 5 ml ) was added in 0.25 ml portions but, for compounds (14) and (15), the portions added were 0.2 ml and then near the equivalence point 0.1 ml portions were added.

Method E. This was similar to method A except that $0.1 \mathrm{~m}-\mathrm{NaOH}$ was used as titrant. In a typical procedure, compound (17) ( 0.101 g ) was dissolved in distilled water $(47.5 \mathrm{ml})$ such that at half-neutralization the concentration of sulphamate was $0.01 \mathrm{~m} . \quad 0.1 \mathrm{~m}-\mathrm{NaOH}(5 \mathrm{ml})$ was added in 0.2 ml portions. Compound (4) ( 0.0473 g ) was dissolved in distilled water ( 22.5 ml ) and titrated with $0.1 \mathrm{M}-\mathrm{NaOH}(2.5$ $\mathrm{ml})$ in 0.25 ml portions. In this method corrections were made in the calculation for varying hydroxide ion concentration and for dilution of the substrate.
Other corrections. Some sulphamates contained water of hydration and in such cases allowance was made for this when weighing out the compound. Occluded water of hydration is a common problem with sulphamates even after thorough drying. ${ }^{13}$ In the few instances where barium (rather than sodium) sulphamates were used allowance was made for the fact that two sulphamate anions are released in solution from each molecule of salt.
${ }^{18} \mathrm{C}$ N.m.r. Measurements.- ${ }^{13} \mathrm{C}$ Spectra were measured on a JEOL JNM FX 60 spectrometer in 10 mm tubes at $28^{\circ} \mathrm{C}$ at 15 MHz with proton decoupling. Chemical shifts $(\mathrm{Hz})$ were determined using $\mathrm{D}_{2} \mathrm{O}$ (internal lock). Resolution, pulse width, and pulse repetition were $0.3 \mathrm{~Hz}, 13 \mu \mathrm{~s}$, and 1.0 s respectively.

Determination of $p \mathrm{~K}_{\mathrm{a}}$ in the $p H$ Region.-The following $* 11=10^{-3} \mathrm{~m}^{3}$.
$\dagger^{\circ} \mathrm{C}=\mathrm{K}-273.15$.
$\ddagger \mathrm{lm}=10^{3} \mathrm{~mol} \mathrm{~m}{ }^{-3}$.
represents the conditions of a typical run. Compound (4) ( 50 mg ) was dissolved in $1.3 \mathrm{M}-\mathrm{HCl}(3 \mathrm{ml})$ and $\mathrm{D}_{2} \mathrm{O}(0.4 \mathrm{ml})$ was added. The initial pH and the chemical shifts of the five carbon atoms were measured. The addition of small volumes of sodium hydroxide ( $4 \mathrm{~m}, 1 \mathrm{~m}$, and 0.5 m ) changed the pH and the chemical shifts. After each addition of base the pH was redetermined, a portion of the solution was withdrawn (and later returned) and added to the n.m.r. tube, and the chemical shifts measured. In order to determine the shifts more rapidly an additional amount (ca. 50 mg ) of compound (4) was added to the more dilute acid media.

Determination of $p \mathrm{~K}_{\mathrm{a}}$ in Strong Acid Media.-The following represents the conditions of a typical run. Compound (17) ( $20-40 \mathrm{mg}$, depending on solubility) was dissolved in a series of sulphuric acid solutions from 1.5 to $17.8 \mathrm{~m}(1.6 \mathrm{ml})$, each solution containing $\mathrm{D}_{2} \mathrm{O}(0.4 \mathrm{ml})$, giving a series of $\mathrm{H}_{2}-$ $\mathrm{SO}_{4}$ solutions from 1.2 to 14.2 m . Two additional measurements were made by (i) dissolving the compound in 17.8 M $\mathrm{H}_{2} \mathrm{SO}_{4}(1.6 \mathrm{ml})-\mathrm{D}_{2} \mathrm{O}(0.2 \mathrm{ml})$ and (ii) in $17.8 \mathrm{M}-\mathrm{H}_{2} \mathrm{SO}_{4}(1.6 \mathrm{ml})-$ $17.8 \mathrm{~m}-\mathrm{D}_{2} \mathrm{SO}_{4}(0.4 \mathrm{ml})$. The chemical shifts of the four different carbon atoms of compounds (17) and (18) were determined in each of the solutions using $\mathrm{C}-4$ as an intramolecular standard. For compound (13) the chemical shifts were determined for all the different carbon atoms.

## RESULTS AND DISCUSSION

Equilibrium b.-In Table $1 \mathrm{p} K_{\mathrm{a}}$ values are given for equilibrium b for 12 sulphamates including three sulphamates of secondary amines. Both potentiometric (methods A and B ) and ${ }^{13} \mathrm{C}$ methods were used to determine ionization data.

Table 1
$\mathrm{p} K_{\mathrm{a}}$ Values at $25^{\circ} \mathrm{C}$ for sulphamates $\mathrm{RNHSO}_{3}{ }^{-}$and $\mathrm{R}^{1} \mathrm{R}^{2} \mathrm{NSO}_{3}{ }^{-}$in equilibrium b

${ }^{a}$ The scatter or spread was calculated as described in ref. 3, ch. 1. ${ }^{b} n=$ No. of $\mathrm{p} K_{a}$ values averaged to obtain the value given; generally the first and the last values were omitted. ${ }^{c} 0.02 \mathrm{~m}-(0.133 \mathrm{~g})$-sulphamate used in 47.5 ml . ${ }^{d} n=$ No. of ways in which the $\mathrm{p} K_{a}$ was calculated from the chemical shift data in the upper part of Table 4; the value given is the average of these values. © Barium salt.

In the calculations based on the potentiometric measurements the $\mathrm{p} K_{\mathrm{a}}$ values were calculated at each pH from equation (1) where $\alpha=\left(\left[\mathrm{Na}^{+}\right]+\left[\mathrm{H}^{+}\right]+\right.$ $[\mathrm{Cl}]) /\left[\mathrm{Na}^{+}\right]$. The spread or scatter ${ }^{3}$ and the number

$$
\begin{equation*}
\mathrm{p} K_{\mathrm{a}}=\mathrm{pH}+\log (1-\alpha) / \alpha \tag{1}
\end{equation*}
$$

of $\mathrm{p} K_{\mathrm{a}}$ values determined in each set are given in Table 1. A $\mathrm{p} K_{\mathrm{a}}$ of $1.13 \pm 0.04$ was determined for sodium
sulphamate in a trial run using a 0.1 m solution (at 50 ml dilution) of the salt. This value is in good agreement with the potentiometrically determined value of Hargreaves ${ }^{14}$ (1.19).

The advantages of ${ }^{13} \mathrm{C}$ over ${ }^{1} \mathrm{H}$ n.m.r. and the methodology involved has been discussed previously. ${ }^{2}$ In the upper part of Table 4 chemical shift differences (in Hz ) for the carbon atoms of compounds (4), (6), and (24) are given. The shifts at $\mathrm{pH} c a .0$ and at $c a .10$ were taken to represent the protonated $\left(\mathrm{BH}^{+}\right)$and unprotonated (B) forms respectively. Chemical shifts were measured at about seven intermediate pH values. For compound (4), the chemical shift difference between C-3 and -4 ( $\mathrm{C}-4$ and -5 are equivalent) varies only slightly over the whole range of pH and thus these carbons were used as intramolecular standards. The $\mathrm{p} K_{\mathrm{a}}$ could then be calculated in four ways utilising the differences $\Delta(4-1)$, $\Delta(4-2), \Delta(3-2)$, and $\Delta(3-1)$ and using equation (2)

$$
\begin{equation*}
\mathrm{p} K_{\mathrm{a}}=\log \left(\Delta \delta-\Delta \delta_{\mathrm{B}}\right) /\left(\Delta \delta_{\mathrm{BH}^{+}}-\Delta \delta\right)+\mathrm{pH} \tag{2}
\end{equation*}
$$

where $\Delta \delta_{\mathrm{BH}^{+}}$is the appropriate chemical shift difference at $\mathrm{pH} c a .0$ and $\Delta \delta_{\mathrm{B}}$ the chemical shift difference for the same pair of carbon atoms at $\mathrm{pH} c a$. 10 . For compound (6) the assignments (other than that for C-1) may not be correct. However, the chemical shifts (upfield and downfield) of the various carbons could be readily followed with the steady deprotonation as base was added. Since the chemical shift differences, $\Delta(4-3)$ and $\Delta(6-3)$, were small over the range of the study the following four shift differences were used to calculate $\mathrm{p} K_{\mathrm{a}}$ values: $\Delta(4-1), \Delta(2-1), \Delta(6-1)$, and $\Delta(3-1)$ for compound (6). For compound (23) $\Delta(4-3$ ) was small and $\mathrm{p} K_{\mathrm{a}}$ values were calculated using the remaining six shift differences shown for (23) in Table 4. The spreads for the three $\mathrm{p} K_{\mathrm{a}}$ values measured by ${ }^{13} \mathrm{C}$ n.m.r. in Table 1 are quite small thus showing that the $\mathrm{p} K_{\mathrm{a}}$ values calculated from the various shift differences for each compound are close. Good sigmoidal plots of $\Delta \delta$ versus pH were obtained in all cases. Two examples are shown in the Figure.

Some features are worthy of note in Table 1. First, the facts that the sulphamates of secondary amines, e.g. (21)-(23), are, as expected, somewhat more basic than those of primary amines, e.g. (1) and (2). Though with
successive substitution some of the latter sulphamates become more basic, e.g. in the series (1), (2), (3), (5), and (8). The reduced basicity of (9) compared with (8) is of interest and could perhaps have been predicted if one could compare the $\mathrm{p} K_{\mathrm{a}}$ values of compound (2) and t -

Variation of chemical shift difference with pH for compound (4), $\Delta(4-1)(\square)$ and for compound (23), $\Delta(4-N)(\Delta)$. The symbol ' $N$ ' is used for the chemical shift of the methyl group attached to nitrogen in (4)
butylsulphamate [regarding the latter compounds as vaguely approximate models for (9) and (8), respectively,] a supposition supported by the virtual identity of the $\mathrm{p} K_{\mathrm{a}}$ values of (9) and (2). Second, the $\mathrm{p} K_{\mathrm{a}}$ values measured by ${ }^{13} \mathrm{C}$ n.m.r. are $0.4-0.6 \mathrm{p} K_{\mathrm{a}}$ units lower than those measured by the potentiometric method. A somewhat similar lowering of the $\mathrm{p} K_{\mathrm{a}}$ was observed earlier when comparing $\mathrm{p} K_{\mathrm{a}}$ values measured by ${ }^{13} \mathrm{C}$ n.m.r. and by the potentiometric method (ca. 0.4), by a conductimetric method (ca.0.3), and by ${ }^{1} \mathrm{H}$ n.m.r. ( $c a$. $0.1) .{ }^{2}$ These differences in the $\mathrm{p} K_{\mathrm{a}}$ values obtained by different methods are most likely due to medium effects. The conditions under which, for example, the ${ }^{13} \mathrm{C}$ and potentiometric measurements were made, are quite different (see Experimental section).

The compounds in Table 2 have hetero-nitrogen ( $\mathrm{p} K_{1}$ ) and sulphamate nitrogen $\left(\mathrm{p} K_{2}\right)$ sites. In the case of

Table 2

compounds (10)—(13) where the basicity of the heteronitrogen is at least six times greater than that of the sulphamate nitrogen equation (1) could be used to calculate $\mathrm{p} K_{1}$ and equation (3) was used to calculate $\mathrm{p} K_{2} .{ }^{4} \quad \mathrm{p} K_{1}$ and $\mathrm{p} K_{2}$ were also calculated for these

$$
\begin{gather*}
\mathrm{p} K_{2}=\log \left(\left[\mathrm{Cl}^{-}\right]-\left[\mathrm{Na}^{+}\right]-\left[\mathrm{H}^{+}\right]\right) /\left(2\left[\mathrm{Na}^{+}\right]-\left[\mathrm{Cl}^{-}\right]+\right. \\
\left.\left[\mathrm{H}^{+}\right]\right)+\mathrm{pH}-\frac{1.5345 I^{\ddagger}}{1+1.6 I^{+}}  \tag{3}\\
I=2\left[\mathrm{Cl}^{-}\right]-\left[\mathrm{Na}^{+}\right]-\left[\mathrm{H}^{+}\right]
\end{gather*}
$$

compounds utilising a computer program designed for the separation of overlapping $\mathrm{p} K_{\mathrm{a}}$ values. The program gave values of $\mathrm{p} K_{1}$ and $\mathrm{p} K_{2}$ in good agreement with those calculated from equations (1) and (3). A test run was carried out with succinic acid using available data ${ }^{4}$ with the following results: $\mathrm{p} K_{1} 4.134$ and $\mathrm{p} K_{2} 5.551$ compared with values of 4.200 and 5.634 , respectively, given by Albert and Sergeant. The program was used to calculate the overlapping $\mathrm{p} K_{1}$ and $\mathrm{p} K_{2}$ values for compounds (14)-(16). The values obtained are given in Table 2. Compound (14) may have its sulphamate nitrogen $\mathrm{p} K_{\mathrm{a}}$ somewhat similar to the $\mathrm{p} K_{\mathrm{a}}$ of compound (4) (1.86, potentiometrically). On this basis we feel that for (14), $\mathrm{p} K_{1}$ is 1.16 and $\mathrm{p} K_{2} 1.96$. Taking the related compounds (15) and (16) together, for (16) 4.55 is assigned to $\mathrm{p} K_{1}$, being too basic to be a sulphamate nitrogen, and $\mathrm{p} K_{2}$ is then 1.05. For compound (15) the two $\mathrm{p} K_{\mathrm{a}}$ values ( 1.33 and 1.90 ) given by the computer indicate that the two sites in this compound are of very similar basicities. To assign $\mathrm{p} K_{1}$ and $\mathrm{p} K_{2}$ we noted that the $\mathrm{p} K_{\mathrm{a}}$ values of morpholine [a model for (15)] ( $\mathrm{p} K_{\mathrm{a}} 8.33^{15}$ ) and piperidine [a model for (16)] ( $\mathrm{p} K_{\mathrm{a}} 11.12^{15}$ ) differed by $2.79 \mathrm{p} K_{\mathrm{a}}$ units and that a value (2.65) close to this difference is obtained if one substracts 1.90 from 4.55 whereas subtraction of 1.33 from 4.55 gives $\mathbf{3 . 2 2}$. We therefore felt that for compound (15), $\mathrm{p} K_{1}$ is 1.90 and $\mathrm{p} K_{2} 1.33$.

Equilibrium a.-Table 3 contains $\mathrm{p} K_{\mathrm{a}}$ values for equilibrium a, i.e. the removal of a proton from sulph-

- Using Method E. ${ }_{\text {e }}{ }^{b, c}$ See footnotes $a, b$ respectively in Table 1. © Barium salt.
amate anions. While there are a number of reports ${ }^{16}$ of dimetallic salts of sulphamic acid, $\mathrm{NHM}^{\prime} \mathrm{SO}_{3} \mathrm{M}$, formed in the reaction $\mathrm{NH}_{2} \mathrm{SO}_{3} \mathrm{M}+\mathrm{M}^{\prime}$ (liq. $\left.\mathrm{NH}_{3}\right) \rightarrow \mathrm{NHM}^{\prime}-$ $\mathrm{SO}_{3} \mathrm{M}$ with $\mathrm{M}^{\prime}=\mathbf{M}$ and $\mathrm{M}^{\prime} \neq \mathrm{M}$ there are no reports of studies of the acidity of the sulphamate nitrogen in $\mathrm{RNHSO}_{3}{ }^{-}$. The sulphamate nitrogen is several $\mathrm{p} K_{\mathrm{a}}$ units more basic than the analogous sulphonamide nitrogen in benzenesulphonamides $\mathrm{XC}_{6} \mathrm{H}_{4} \mathrm{SO}_{2} \mathrm{NH}_{2}\left(\mathrm{p} K_{\mathrm{a}}\right.$ $9-10.5^{17}$ ) and in benzenesulphonanilides $\mathrm{ArSO}_{2} \mathrm{NHAr}$
( $\mathrm{p} K_{\mathrm{a}} 6.2-9^{17}$ ). This larger basicity can be rationalized in terms of the electrostatic repulsion created in the sulphamate dianion by the proximity of the two negative charges.

The $\mathrm{p} K_{\mathrm{a}}$ values were calculated from equation (4) where

$$
\begin{align*}
& {\left[\mathrm{B}^{-}\right]=\left[\mathrm{RNSO}_{3}^{-}\right] \text {and }[\mathrm{B}]=\left[\mathrm{RNHSO}_{3}^{-}\right]} \\
& \mathrm{p} K_{\mathrm{a}}=\mathrm{pH}+\log \left([\mathrm{B}]+\left[\mathrm{B}^{-}\right]+\right. \\
& \left.\left[\mathrm{OH}^{-}\right]\right) /\left(\left[\mathrm{B}^{-}\right]-\left[\mathrm{OH}^{-}\right]\right) \tag{4}
\end{align*}
$$

Equilibrium c.-Ionization data were calculated from equation (5) where $\Delta v_{\mathrm{BH}_{2}+}$ and $\Delta v_{\mathrm{BH}^{+}}$are the chemical shift differences of the diprotonated sulphamates $\mathrm{RNH}_{2} \mathrm{SO}_{3} \mathrm{H}$ and the zwitterionic sulphamate, $\mathrm{RNH}_{\mathbf{H}_{2}}$ $\mathrm{SO}_{3}{ }^{-}$, respectively. The shifts at 17.8 m - and $1.2 \mathrm{~m}-$ $\mathrm{H}_{2} \mathrm{SO}_{4}$ were taken to represent the diprotonated and zwitterionic forms respectively.

$$
\begin{equation*}
I=\left(\Delta v_{\mathrm{BH}^{+}}-\Delta v\right) /\left(\Delta v-\Delta v_{\mathrm{BH}_{\mathbf{2}}+}\right) \tag{5}
\end{equation*}
$$

The $\mathrm{p} K_{\mathrm{a}}$ for compound (17) was determined from the chemical shift difference $\Delta(3-1)$. The signals due to C-3 and -4 partially overlap in very strong acid. $\Delta(3-2)$ varies only slightly over the range of acidities involved so that $\mathrm{C}-2$ could also be used as an intramolecular standard. For compound (18) $\mathrm{p} K_{\mathrm{a}}$ was determined using $\Delta(4-1)$. $\quad$ C- 3 or -2 also appear to be suitable intramolecular standards. For compound (13), the signals due to C-2, $-3,-4^{\prime}$, and $-5^{\prime}$ were assigned by comparison with $N$-ethylmorpholine. ${ }^{18}$ The assignments are supported by the fact that the chemical shift difference $\Delta\left(v_{\mathrm{BH}^{+}}-v_{\mathrm{B}}\right)$ for $\Delta(2-1)$ were of the same sign and magnitude as those for compound (18). The $\mathrm{p} K_{\mathbf{B H}_{\mathbf{3}}+}{ }^{+}$ value for the sulphamate oxygen was determined from $\Delta(2-1)$ as it was desired to minimize interference due to simultaneous protonation of the morpholine oxygen. $\Delta(4-2)$ was used to calculate a $\mathrm{p} K_{\mathrm{a}}$ value for the morpholine oxygen as this shift gave the largest and most regular pattern of change with varying acidity. An uncertainty existed as to which acidity corresponds to $\Delta v_{\mathrm{B}}$. The chemical shift differences were seen by inspection to be tapering off near $1.96 \mathrm{~m}-\mathrm{H}_{2} \mathrm{SO}_{4}$ but between this acidity and $1.5 \mathrm{M}-\mathrm{H}_{2} \mathrm{SO}_{4}$ a relatively large change took place. This we attribute to the commencement of deprotonation of the sulphamate nitrogen of (13) which may be expected to begin to lose its proton at ca. $1.5 \mathrm{M}-\mathrm{H}_{2} \mathrm{SO}_{4}$. Accordingly, we have taken the chemical shift differences at $1.96 \mathrm{M}-\mathrm{H}_{2} \mathrm{SO}_{4}$ to represent $\Delta v_{\mathrm{B}}$.

Plots of $\log _{10} I$ versus $-H_{0}$ [equation (6)] gave slopes $m$ much lower than unity. The first column in Table 5 gives the values obtained as $\mathrm{d} \log _{10} I / \mathrm{d}\left(-H_{0}\right)$. These values show clearly that $H_{0}$ is not followed. The $\left(H_{0}\right)_{ \pm}$

$$
\begin{equation*}
\log _{10} I=-m H_{0}+\mathrm{p} K_{\mathrm{BH}_{2}}{ }^{+} \tag{6}
\end{equation*}
$$

values have been calculated using equation (6), when $\left[\mathrm{BH}^{+}\right]=\left[\mathrm{BH}_{2}^{+}\right]$, i.e. the situation at half-protonation. Then, $-m\left(H_{0}\right)_{2}=\mathrm{p} K_{\mathrm{BH}_{4}+}$ and if the intercept of equation $(6)$ is obtained and divided by the slope $(m),\left(H_{0}\right)_{\frac{1}{2}}$ values are obtained. $-m\left(H_{0}\right)_{\frac{1}{2}}$ Values are also given. When

${ }^{a}$ The symbol ' N ' is used for the chemical shift of the methyl group attached to nitrogen in (4).
the benzophenone acidity function ( $H_{0}{ }^{\text {a }}$ ) was used the points gave a slightly better fit to a straight line but the $m$ values were still $c a .0 .25$. If $H_{\mathrm{A}}$ was used instead of $H_{0}$ in equation (6), the slopes ( $m$ ) were ca. 0.5. The most suitable function appears to be the alcohol acidity function, $H_{\mathrm{ROH}} .{ }^{19} \quad$ The slopes $(m)$ of plots of $\log _{10} I$ versus $-H_{\mathrm{ROH}}$ are closer to unity than in the case of the other functions. The $\mathrm{p} K_{\mathrm{BH}_{2}{ }^{+}}$values obtained with this function are given in Table 5. These values are also in
values for compound (17) of $-1.79\left(n_{\mathrm{B}} 1.30\right)$ and -1.67 ( $m^{*} 0.19$ ) respectively.

From the chemical shift differences for compound (13) the $\mathrm{p} K_{\mathrm{a}}$ for its morpholine oxygen can also be calculated. Using $H_{0}$, the slope of $\log _{10} I$ versus $-H_{0}$ is 0.20 and the $\mathrm{p} K_{\mathrm{a}}$ value estimated from this is -1.0 . Using $H_{\mathrm{ROH}}$, a slope of 0.72 with a $\mathrm{p} K_{\mathrm{a}}$ of -1.25 is obtained. This latter value is in reasonable agreement with the Bunnett and Olsen value from equation (7), -1.45. For satur-

\end{equation*}
$$

There is one report in the literature on the study of equilibrium c for a series of meta- and para-substituted phenylsulphamates. ${ }^{20}$ From the analysis of kinetic data for the acid-catalysed hydrolysis of these compounds, the Russian group have calculated $\mathrm{p} K_{\mathrm{BH}_{2}+}$ values for six phenylsulphamates. The values obtained vary from $-2.67(3-\mathrm{Cl})$ to $-2.04\left(4-\mathrm{CH}_{3} \mathrm{O}\right)$ and $H_{\mathrm{A}}$ appears to be followed quite well. In equilibrium $b$ arylsulphamates are more weakly basic than aliphatic and alicyclic sulphamates ${ }^{1}$ and not surprisingly this is also the case (though to a lesser extent) in equilibrium c.

Marziano ${ }^{21}$ and Cox-Yates ${ }^{22}$ plots gave $\mathrm{p} K_{\mathrm{BH}_{4}+}$
ated cyclic ethers values somewhat more negative than this (ca. -2 to -2.8 ) have been reported ${ }^{23}$ or can be calculated. ${ }^{24}$ The $\phi$ values in Table 5 are, however, in the area typical for oxygen centres. ${ }^{25}$
