

## Addition of Cyanide Ions to Aromatic Aldehydes: a Competition Method for the Determination of Equilibrium Constants of Nucleophilic Addition Reactions

Victor Gold\* and Wasfy N. Wassef

Department of Chemistry, King's College London, Strand, London WC2R 2LS

The equilibrium concentration of the cyanide Meisenheimer adduct of 1,3,5-trinitrobenzene, formed from potassium cyanide-18-crown-6 and trinitrobenzene, in DMSO solution, is reduced in the presence of an aromatic aldehyde, with an accompanying decrease in the absorbance of the solution due to the intensely coloured Meisenheimer adduct. Equilibrium constants have accordingly been determined for the formation of the cyanide Meisenheimer adduct of trinitrobenzene and for the formation of members of a series of substituted benzaldehyde cyanohydrin anions in dimethyl sulphoxide solution.

Equilibrium constants for the addition of nucleophiles to carbonyl compounds can be determined either directly, by spectroscopic observation of the concentration of one or more of the chemical species involved in the equilibrium, or by measurement of rate constants of the reactions in the forward and reverse directions.<sup>1</sup> The present paper describes an indirect method for determining the equilibrium constant, by monitoring an 'indicator' equilibrium, and the results obtained by this method for the addition of cyanide ions in dimethyl sulphoxide (DMSO) solution to aromatic aldehydes. Cyanide ions add reversibly<sup>2</sup> to 1,3,5-trinitrobenzene (TNB) with formation of a coloured Meisenheimer adduct (I).<sup>3</sup> Spectrophotometric determination of the concentration of the adduct (I) allows evaluation of the equilibrium constant of reaction (1).

When the equilibrium (1) is established in the presence of an aldehyde, the reversible reaction (2) provides an alternative destination for the reactive cyanide. Concentrations are chosen so that the equilibrium concentration of free cyanide ions is negligible compared with that of the Meisenheimer adduct anion (I) or the cyanohydrin anion (II). The concentration of (I) then provides a probe for the position of the equilibrium (3). The

equilibrium constants of the three reactions are related according to equation (4). In the absence of added aldehyde, the

$$K_3 = K_2/K_1 = \frac{[\text{TNB}]}{[\text{ArCHO}]} \cdot \frac{[(\text{II})]}{[(\text{I})]} \quad (4)$$

observed concentration of (I) is equal to the stoichiometric concentration of added cyanide ion  $[\text{CN}^-]_{\text{st}}$ , provided  $[(\text{I})] \gg [\text{CN}^-] \ll [\text{TNB}]$  (the subscript st indicates a stoichiometric concentration). When aldehyde is present, the concentration of (I) is reduced by the equilibrium concentration of (II) in the system. Accordingly, if  $A^\circ$  and  $A$  represent the absorbance [due

Figure 1. Illustration of quantitative conversion of cyanide ion into Meisenheimer adduct (I) at high concentration of TNB ( $2 \times 10^{-3} \text{M}$ )

to (I)] in the absence and presence of added aldehyde, respectively, equation (5) applies. Since  $[\text{TNB}]_{\text{st}} \gg [\text{CN}^-]_{\text{st}} \ll$

$$\frac{A^\circ - A}{A} = \frac{[(\text{II})]}{[(\text{I})]} \quad (5)$$

$[\text{ArCHO}]_{\text{st}}$ , we may equate the stoichiometric and equilibrium concentrations for the two species present in relatively high concentrations, so that equations (4) and (5) give (6).

$$K_3 = \frac{[\text{TNB}]_{\text{st}}}{[\text{ArCHO}]_{\text{st}}} \cdot \frac{(A^\circ - A)}{A} \quad (6)$$

The cyanohydrin anions (II) are moderately strong bases, with (aqueous)  $\text{p}K_{\text{a}}$  values in the range 10.2–10.9.<sup>6</sup> In dry DMSO solutions their rapid protonation by solvent is not expected, nor does their addition to TNB appear to occur at a rate comparable with that of the reactions of interest.

The present paper is concerned with the application of equation (6) to the reaction between the members of a series of substituted benzaldehydes and potassium cyanide (with equimolar addition of 18-crown-6) in DMSO solution at 25 °C.

The procedure utilised is a thermodynamic counterpart of the kinetic competition method applicable when the competing reactions are, for practical purposes, irreversible.<sup>7</sup>

### Experimental

The purification of DMSO, TNB, and aldehydes has previously been described. 18-Crown-6 was purified by complexation with acetonitrile.<sup>8</sup> A stock solution in DMSO containing potassium cyanide and 18-crown-6 in equal concentration (0.01M) was used. Appropriate amounts of the stock solution were added from a syringe to a well stirred solution of TNB at 25 °C. The absorbance of the solution was monitored in cells of 1 cm pathlength at 570 nm on a Pye-Unicam SP8-100 spectrophotometer. Its value immediately rose after mixing, too rapidly for rate measurements on that instrument. The absorption spectrum of the product solution was closely similar to that previously reported for (I) in different solvents.<sup>2,9</sup> The absorbance very slowly decreased with time, and the maximum value recorded almost immediately upon mixing was taken to be that corresponding to the equilibrium concentration of (I). All stock solutions were protected from light.

For solutions of cyanide-crown containing a relatively high concentration of TNB ( $2 \times 10^{-3}$ M), without added aldehyde, the absorbance was proportional to the concentration of cyanide, indicating quantitative formation of (I) (Figure 1) with a molar absorption coefficient  $\epsilon$   $2.18 \times 10^4$  l cm<sup>-1</sup> mol<sup>-1</sup>. At much lower concentrations of TNB the absorbance varies with the concentration of the reactants in a manner consistent with

**Table 1.** Absorbance measurements at low stoichiometric concentrations of cyanide ion\* ( $5 \times 10^{-5}$ M) and TNB

<sup>a</sup> This work. <sup>b</sup> Ching and Kallen.<sup>6</sup> Data for 25 °C and  $I = 1$ .

Results for measurements with aldehydes are given in Table 2, where  $A^\circ$  and  $A$  are the observed absorbances in the absence and in the presence of added aldehyde. From the slopes of graphs (Figure 3) of  $(A^\circ - A)/A$  against  $[\text{ArCHO}]_{\text{st}}/[\text{TNB}]_{\text{st}}$  at low concentrations, values of  $K_3$  were obtained according to equation (6). The equilibrium constants  $K_2$  were calculated *via* equation (4) using the above value of  $K_1$ .

### Discussion

The use of equations (6), (7), and (4) for the evaluation of the equilibrium constants for reactions (1)–(3), respectively, has been demonstrated in the Experimental section. The usefulness of the procedure depends on the high molar absorption coefficient of (I), which allows the measurements to be carried out on very dilute solutions.

Equilibria involving cyanide ions as a nucleophile have frequently been studied in the past. A variety of solvents have been used but the present study appears to be the first one using DMSO. To minimise possible effects of ion association between potassium and cyanide ions, we have followed the stratagem of

Figure 4.  $\rho$ - $\sigma$  and  $\rho$ - $\sigma^+$  correlations for  $K_2$  values

carrying out the measurements in the presence of an equimolecular concentration of 18-crown-6.<sup>10</sup> It has previously been shown that the value of  $K_1$  varies between 39 (in methanol) and  $5 \times 10^5$  (in *t*-butyl alcohol) for a series of alcoholic solvents.<sup>9</sup> This trend can be associated both with the decreasing permittivity of the media and with their decreasing hydrogen bond donor strengths; both factors reduce the stability of the cyanide ion relative to (I) along the series. The solvation of anions is thought to be particularly weak in DMSO, despite its moderately high permittivity, and the high value of  $K_1$  observed in this solvent ( $1.2 \times 10^5 \text{ l mol}^{-1}$ ) is consistent with this view.

Similarly, values of  $K_2$  are large compared with previously determined values relating to aqueous solution.<sup>6</sup> Results for both media are given in Table 3. Plots of  $\lg K_2$  against  $\sigma$  or  $\sigma^+$  (Figure 4) lead to  $\rho$  values (given in Table 3) that are considerably lower for DMSO as solvent. Either plot has been used in the past for similar systems. In the present case the  $\rho$ - $\sigma$  correlation appears to be more closely obeyed. The  $\rho$ -values are numerically smaller than for equilibria involving the addition of hydroxide<sup>11</sup> or methoxide anions<sup>12</sup> (in their respective solvents) to aromatic aldehydes. All these data further exemplify the rather special position of DMSO (and perhaps of similar non-hydroxylic media of relatively high permittivity) as a solvent for enhancing the reactivity (kinetic and thermodynamic) of anionic nucleophiles, an effect which has already extensively been exploited for the n.m.r. observation of Meisenheimer adducts.<sup>13</sup>

### Acknowledgements

We thank Dr. P. J. Atkins for many helpful discussions and Ain Shams University, Egypt, for granting leave of absence to W. N. W. Professor W. P. Jencks kindly drew our attention to some relevant references.
