# Structure and Properties of 1 -Phospha-allene ( $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ ). $\alpha$-Carbon versus Phosphorus Protonation? 

Minh Tho Nguyen and Anthony F. Hegarty*<br>Department of Chemistry, University College, Belfield, Dublin 4, Ireland

#### Abstract

Although 1 -phospha-allenes ( $>\mathrm{C}=\mathrm{C}=\mathrm{P}-$ ) are generally only isolable when bulky groups are present, the first experimental data are now becoming available. $A b$ initio calculations are reported for this novel cumulene system ( $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ ) and four possible protonated analogues. The phospha-allene is configurationally stable with a large rotational barrier. The contribution of structures such as (1b) are minimal; in fact the $\mathrm{C}=\mathrm{C}$ and $\mathrm{C}=\mathrm{P}$ bonds are largely as in the uncumulated systems, in line with the failure to observe i.r. absorptions in the $1600-2300 \mathrm{~cm}^{-1}$ region. The $\alpha$-carbon is the favoured site of protonation; this behaviour is contrasted with other cumulenes such as ketenimines or phosphaketenes. The proton affinity of 1 -phospha-allene is calculated to be $193 \pm 5 \mathrm{kcal}_{\mathrm{mol}}{ }^{-1}$ at $\mathrm{MP4} / 6-31 \mathrm{G}^{* *} / / \mathrm{HF} / 4$ 31 G . The predicted reactivity of the phospha-allene in cycloadditions and with reagents HX is commented on.

The preparation of dico-ordinated phosphorus-containing compounds has in the past much intrigued the synthetic chemist for several reasons including the reluctance of $P$ atoms to form $p \pi-p \pi$ multiple bonds. Recently, several authors have been successful in designing efficient routes for the preparation of phosphacumulenes of general formula $\mathrm{X}=\mathrm{C}=\mathrm{P}-\left(\mathrm{X}=-\mathrm{N},{ }^{1-3 a}\right.$ $\mathrm{O},{ }^{4 a} \mathrm{C},{ }^{3.4 b}-\mathrm{P}^{3 b .5}$ ). Although these compounds are in general only isolable because of the steric protection provided by bulky substituents, such as $2,4,6$-tri-t-butylphenyl, they are however able to undergo a wide range of chemical transformations at the multiple bonds. As with other phosphorus-containing compounds in low co-ordination state, phospha-allenes appear to possess unusual physico-chemical properties. In this connection, theoretical studies are more than helpful in interpreting the new data, assignment of spectroscopic parameters, and in predicting reactive sites and thereby could stimulate further experimental work.

Recent theoretical studies ${ }^{6}$ on model iminomethylenephosphine ( $\mathrm{HP}=\mathrm{C}=\mathrm{NH}$ ) and 1,3-diphospha-allene ( $\mathrm{HP}=\mathrm{C}=\mathrm{PH}$ ) suggested a difference between their chemical behaviour towards cycloaddition, addition, and metal complexation reactions. We now report on the 1-phospha-allenes (ethenylidenephosphines) ( $>\mathrm{C}=\mathrm{C}=\mathrm{P}-$ ) which are the phosphorus analogues of the ketenimines. The first substituted ethenylidenephosphines have recently been isolated by the groups of Yoshifuji ${ }^{3 a}$ and of Appel ${ }^{4 b}$ and some spectroscopic data are now available. Our aim in the present work is to examine in some detail the geometry, the vibrational frequencies, the configurational stability, the sites of protonation, and the reactivity towards some chemical reagents by means of ab initio calculations on the model molecule $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$. In particular, we wish to establish the similarities and the differences between phospha-allene and ketenimine ( $\quad \mathrm{C}=\mathrm{C}=\mathrm{N}-$ ) for which both extensive experimental ${ }^{7}$ and theoretical ${ }^{8-10}$ studies have previously been reported.

Geometries of stationary structures were determined employing the analytical gradient procedure ${ }^{11}$ and the 4-31G basis set. ${ }^{12}$ Improved relative energies were obtained from single-point calculations (with 4-31Gs geometries) which employ the $6-31 \mathrm{G}^{* * 13 a}$ and a double-zeta plus polarization ${ }^{13 b}$ basis sets. The correlation energies have also been taken into account via the Møller-Plesset perturbation theory to second, third, and fourth order ${ }^{14}$ (with 6-31G** basis set).

The full harmonic force field $(4-31 \mathrm{G})$ for $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ was computed by gradient difference using the VA05AD subroutines. ${ }^{15}$ The harmonic frequencies and normal co-ordinates
were calculated by the standard GF matrix method. ${ }^{16}$ The calculations were performed making use both Monstergauss ${ }^{17 a}$ and Gaussian $80^{17 b}$ programs in their IBM/VM-CMS versions. Optimized geometries are displayed within the text.

## Results and Discussion

(1) Geometry.-The 1-phospha-allene molecule (1) is calculated to have $C_{s}$ symmetry. The $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}$ moiety is nearly the same as that of the ketenimine molecule $\left(\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}\right) .^{8}$ The PH bond length and the CPH bond angle are both in their ordinary order of magnitude. The $4-31 \mathrm{G} C=P$ bond length of $1.657 \AA$ is situated in between those in $\mathrm{HN}=\mathrm{C}=\mathrm{PH}(1.718 \AA$ ) and $\mathrm{HP}=\mathrm{C}=\mathrm{PH}(1.644 \AA)^{6}$ and quite close to that of $1.672 \AA$ in $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH} .{ }^{6}$ By comparison, note that the difference between the calculated (4-31G) $\mathrm{C}=\mathrm{N}$ bond lengths in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}(1.219$ $\AA)^{8}$ and in $\mathrm{H}_{2} \mathrm{C}=\mathrm{NH}(1.256 \AA)^{6}$ is somewhat larger.

In a recent $X$-ray crystallographic study on the $\mathrm{Ph}_{2} \mathrm{C}=\mathrm{C}=\mathrm{P}-$ Ar ( $\mathrm{Ar}=2,4,6$-tri-t-butylphenyl) compound, Appel et al. ${ }^{4 b}$ reported the values of $1.31 \AA$ for $\mathrm{C}=\mathrm{C}$ and $1.63 \AA$ for $\mathrm{C}=\mathrm{P}$. We note that the sums of the $\mathrm{C}=\mathrm{C}$ and $\mathrm{C}=\mathrm{P}$ distances in both cases are almost the same.
(2) Configurational Stability.-Like ketenimines, 1-phosphaallenes are axially dissymmetrical. However, according to the computed barriers to rotation $\left(47.5 \mathrm{kcal} \mathrm{mol}^{-1}\right.$ at $4-31 \mathrm{G}$ and $48.5 \mathrm{kcal} \mathrm{mol}^{-1}$ at DZP//4-31G, see Table 1) with the transition structure (2), 1-phospha-allene is rather stable towards configurational change. This barrier to rotation can be compared

Table 1. Calculated total (a.u.) and relative ( $\mathrm{kcal} \mathrm{mol}^{-1}$ ) energies of three forms of 1-phospha-allene at both 4-31G//4-31G and DZP//4-31G levels

|  |  | Total energies |  | Relative energies |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 4-31G//4-31G | DZP//4-31G | 4-31G | DZP |
| (1) |  | -417.60136 | -418.134 31 | 0.0 | 0.0 |
| (2) | (rotation) | -417.525 53 | -418.05694 | 47.6 | 48.5 |
| (3) | (inversion) | -417.47684 | -418.000 26 | 78.1 | 84.1 |

with related systems: $42 \mathrm{kcal} \mathrm{mol}^{-1}$ (DZP//4-31G) in diphosphaallene ( $\mathrm{HP}=\mathrm{C}=\mathrm{PH}$ ), ${ }^{6} 75.3 \mathrm{kcal} \mathrm{mol}^{-1}$ in phosphaethene $\left(\mathrm{H}_{2} \mathrm{C}=\right.$ $\mathrm{PH}, 4-31 \mathrm{G} / / 4-31 \mathrm{G}){ }^{18} 60 \mathrm{kcal} \mathrm{mol}^{-1}$ in diphosphene $(\mathrm{HP}=\mathrm{PH}$, DZP//3-21G). ${ }^{19} \mathrm{~A}$ similar situation has already been met for the $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH} / \mathrm{H}_{2} \mathrm{C}=\mathrm{NH}$ pair of molecules where the barrier to inversion is 13.9 and $32.4 \mathrm{kcal} \mathrm{mol}^{-1}$ at $6-31 \mathrm{G}^{* *} / / 4-31 \mathrm{G}$, respectively.

For 1-phospha-allene (1), the interconversion process via the rotation transition structure (2) is noticeably favoured relative to the inversion transition structure (3) by ca. $30-36 \mathrm{kcal} \mathrm{mol}^{-1}$ (see Table 1); for comparison the difference is only $6 \mathrm{kcal} \mathrm{mol}^{-1}$ (4-31G) in $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH}^{18}$ and $10 \mathrm{kcal} \mathrm{mol}^{-1}$ (DZP) in $\mathrm{HP}=\mathrm{PH} .{ }^{19}$

The Figure displays the orbital correlation diagram calculated at DZP//4-31G level for the LUMOs and four HOMOs of different structures including three forms (1)-(3) of $\mathrm{H}_{2} \mathrm{C}=$ $\mathrm{C}=\mathrm{PH}$, both perpendicular (4) (minimum) and linear (5) (inversion transition structure) forms of $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}$, and finally $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH}(6)$ and $\mathrm{H}_{2} \mathrm{C}=\mathrm{NH}$ (7).

The linearization of the hydrogen atom on the phosphorus in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ (1)-(3) destabilizes both $\pi$ and $n$ HOMOs. However, the rotation of the PH bond in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}(1)$ to (2) and the inversion of the nitrogen atom in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}$ (4) to (5) create two opposite effects: the one destabilizing the highest occupied orbitals ( $n$ character in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}$ and $\pi$-character in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ ) and the other stabilizing the immediately subsequent occupied orbitals ( $\pi$ in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}$ and $n$ in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ ).

Very recently, an activation free energy of $20.3 \mathrm{kcal} \mathrm{mol}^{-1}$ has been reported ${ }^{20}$ for the $Z-E$ isomerization in the bis-(2,4,6-tri-tbutylphenyl)diphosphene ( $\mathrm{ArP}=\mathrm{PAr}$ ). It can be expected that the aromatic rings could stabilize appreciably the $n$-orbitals by the inductive effect and tend to limit the destabilization of the $\pi$ orbitals by conjugation.

From the energetic data of (1) and (2) as presented in Table 1 and the Figure, we may predict that for the radical cation $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}^{+*}$, both perpendicular and planar structures are close in energy. The radical cation might even have the planar configuration as a minimum.
(3) Electronic Structure.-The ground-state electronic configurations of 1-phospha-allene (1) and ketenimine (4) are as follows:
$\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}(1):\left(1 a^{\prime \prime}\right)^{2}\left(7 a^{\prime}\right)^{2}\left(8 a^{\prime}\right)^{2}\left(2 a^{\prime \prime}\right)^{2}\left(9-12 a^{\prime}\right)^{8}\left(3 a^{\prime \prime}\right)^{2}\left(4 a^{\prime \prime}\right) \ldots$ $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}(4):\left(1 a^{\prime \prime}\right)^{2}\left(7 a^{\prime}\right)^{2}\left(8 a^{\prime}\right)^{2}\left(2 a^{\prime \prime}\right)^{2}\left(9 a^{\prime}\right)^{2}\left(3 a^{\prime \prime}\right) \ldots$

As mentioned above, the HOMO in (1) as well as in $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH}$ (6) is the $\pi$-orbital of the $\mathrm{C}=\mathrm{P}$ bond (with the largest coefficient on the P atom) while in (4), as well as in $\mathrm{H}_{2} \mathrm{C}=\mathrm{NH}$ (7), the HOMO is the $n$-orbital of the nitrogen atom. Unlike $\mathrm{HP}=\mathrm{C}=\mathrm{NH}$ and $\mathrm{HP}=\mathrm{C}=\mathrm{PH}$ where the $\pi_{\mathrm{CP}}$ and $n_{\mathrm{P}}$ HOMOs are quasi-degenerate, ${ }^{6}$ a significant $n-\pi$ separation of 0.6 eV in (1) has been calculated. Nevertheless, this orbital energy difference is much smaller than that of 3.15 eV observed in ketenimine (4) (see Figure). It is also worth noting that both $n$ and $\pi$ orbitals in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ (1) are little perturbed with respect to those of the

Figure. Orbital correlation diagram for the LUMO and some HOMOs in three forms (1)-(3) of $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$, two forms (4) and (5) of $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}, \mathrm{H}_{2} \mathrm{C}=\mathrm{PH}$ (6), and $\mathrm{H}_{2} \mathrm{C}=\mathrm{NH}$ (7) calculated at the $\mathrm{DZP} / 4$ 31G level
uncumulated $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH}$ (6), in clear contrast to the situation in $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}$ (4). As seen in Table 2, the overlap population of the $C=P$ bond in (1) is nearly equal to that of (6).

The following is the decrease in the $\mathrm{C}=\mathrm{P}$ bond populations in different compounds: ${ }^{6} \quad \mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ (1.16) $\sim \mathrm{H}_{2} \mathrm{C}=\mathrm{PH}$ (1.18) $>\mathrm{HPC}=\mathrm{PH}(0.86) \sim \mathrm{HNC}=\mathrm{PH}(0.85)$. The P atom in (1) is less positively charged than that in (4) but the charge of 0.13 is still significantly positive by comparison with those of $0.02 \mathrm{e}^{-}$in $\mathrm{HP}=\mathrm{C}=\mathrm{PH}$ and $-0.01 \mathrm{e}^{-}$in $\mathrm{HN}=\mathrm{C}=\mathrm{PH} .^{6}$ This electronic distribution is consistent with the n.m.r. data. The observed ${ }^{31} \mathrm{P}$ chemical shift, $\delta_{\mathrm{P}} 72$ p.p.m., in $\mathrm{Ph}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PAr}^{3 \mathrm{a}}$ is not very low by comparison with those of phospha-alkenes ( $>\mathrm{C}=\mathrm{P}-$, usually $\delta_{\mathrm{P}}>200$ p.p.m.). In contrast, the peaks in the carboimidophosphenes ( $-\mathrm{N}=\mathrm{C}=\mathrm{P}-$ ) are situated at high field, $\delta_{\mathrm{P}} c a .-65$ to 100 p.p.m. ${ }^{1,3}$

The $\alpha$-carbon is the most negatively charged atom in the 1-phospha-allene (1) and the charge on this carbon decreases in the following sequence: $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH}(-0.49)>\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ $(-0.34)>\mathrm{HP}=\mathrm{C}=\mathrm{PH}(-0.14)>\mathrm{HN}=\mathrm{C}=\mathrm{PH}(-0.06)$. In summary, the cumulation with a $\mathrm{C}=\mathrm{C}$ double bond products little modification on the electronic structure of the $\mathrm{C}=\mathrm{P}$ bond.
(4) Molecular Properties.-The dipole moment of 1.44 D of (1) is slightly larger than the value of 1.02 D for $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH}$ at the same DZP//4-31G level (Table 3). That is no doubt due to the small but positive contribution of the negative charge at the $\beta$ carbon in (1) in reinforcing the dipole $\stackrel{\stackrel{-}{\mathrm{C}}}{\mathbf{1}} \stackrel{+}{\mathrm{P}}$. In contrast, the dipole moment of (4) is found to be smaller than that of 2.18 D of $\mathrm{H}_{2} \mathrm{C}=\mathrm{NH} .{ }^{6}$ Table 2 indicates that this

${ }^{a}$ In parentheses are the values obtained for $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}$ with a $\mathrm{Cl} / \mathrm{DZP}$ wave function taken from ref. $9 .{ }^{b}$ In principal axis systems. ${ }^{\text {c }}$ Asymmetric parameters.
reduction could arise from a partial cancellation of the dipoles of the $\mathrm{N}-\mathrm{H}$ bond and the whole $\mathrm{C}=\mathrm{C}=\mathrm{N}$ group. The second moment $\left\langle r^{2}\right\rangle$ shows that the extent of the charge distribution in the ketenimine (4) is about two-thirds as large as that of 1 -phospha-allene (1). The $\langle 1 / r\rangle$ values indicate that the potential at the carbon nucleus remains unchanged in both positions ( $\alpha$ and $\beta$ ) and in both structures (1) and (4). Finally, the electric field gradient $g_{z z}$ of the P atom in (1) is predicted to be the smallest value among those of the molecules considered, namely: $\mathrm{H}_{2} \mathrm{CC}=\mathrm{PH}(0.968)<\mathrm{HPC}=\mathrm{PH}(1.123)<\mathrm{HNC}=\mathrm{PH}$ (1.131) $<\mathrm{H}_{2} \mathrm{C}=\mathrm{PH}$ (1.384). This decrease for $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ suggests a similar decrease of the ionic character of the $\mathrm{C}=\mathrm{P}$ bond through cumulation: $\mathrm{H}_{2} \mathrm{C} \overline{\mathrm{C}}-\stackrel{+}{\mathrm{P}} \mathrm{H}<\mathrm{HP} \overline{\mathrm{C}}-$ $\stackrel{+}{\mathrm{P}} \mathrm{H}<\mathrm{HN} \overline{\mathrm{C}}-\stackrel{+}{\mathrm{P}} \mathrm{H}<\mathrm{H}_{2} \stackrel{-}{\mathrm{C}}-\stackrel{+}{\mathrm{P}} \mathrm{H}$. In other words, the resonance structures ( $\mathbf{1} \mathbf{a}$ and $\mathbf{b}$ ) are only minor contributors to the overall structure of the 1 -phospha-allene molecule by comparison with other phosphacumulenes.

$$
\underset{\text { (1) }}{\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}} \longleftrightarrow \underset{\text { (1a) }}{\mathrm{H}_{2} \mathrm{C}=-\overline{\mathrm{C}}-\stackrel{+}{\mathrm{P}} \mathrm{H}} \longleftrightarrow \underset{\text { (1b) }}{\mathrm{H}_{2}-\overline{\mathrm{C}}-\mathrm{C} \equiv \stackrel{+}{\mathrm{P}} \mathrm{H}}
$$

The situation in ketenimine (4) is somewhat different. The sequence of $q_{z z}\left({ }^{14} \mathrm{~N}\right)$ values is: $\mathrm{HNC}=\mathrm{NH}(0.662)<\mathrm{H}_{2} \mathrm{CC}=\mathrm{NH}$ ( 0.800 ) $<\mathrm{H}_{2} \mathrm{C}=\mathrm{NH}$ (1.117). Consequently, an increasing ordering of ionic character may be noted: $\mathrm{H}_{2} \stackrel{+}{\mathrm{C}}-$ $\overline{\mathrm{N}} \mathrm{H}<\mathrm{H}_{2} \mathrm{C} \stackrel{+}{\mathrm{C}}-\overline{\mathrm{N}} \mathrm{H}<\mathrm{HP} \stackrel{+}{\mathrm{C}}-\overline{\mathrm{N}}^{\mathrm{H}}<\mathrm{HN} \stackrel{+}{\mathrm{C}}-\overline{\mathrm{N}}^{-} \mathrm{H}$.
(5) Vibrational Frequencies.-The 4-31G harmonic frequencies are collected in Table 4. It is well established that harmonic

force fields of molecules containing first-row atoms $(\mathrm{H}, \mathrm{C}, \mathrm{N}, \mathrm{O}$, F) calculated at SCF level of theory with double-zeta or splitvalence basis set provide vibrational frequencies systematically overestimated by about $10 \%$ with respect to the experimental values. ${ }^{21}$ On the other hand, it was recently shown that the stretching frequencies of $\mathrm{P}=\mathrm{X}$ multiple bonds are slightly underestimated by 4-31G calculations. ${ }^{22,23}$ For this reason, we consider here an average scale factor of $v$ (predicted) $/ v(4$ $31 G)=0.9$ for the vibrational modes of the $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}$ moiety in order to predict more realistic frequencies (Table 4).

In their experimental works, Yoshifuji et al. ${ }^{3}$ have reported an i.r. ( KBr ) spectrum of the $\mathrm{Ph}_{2} \mathrm{C}=\mathrm{C}=\mathrm{P}-\mathrm{Ar}$. The most striking feature of this i.r. spectrum is that there are no significant bands in the region $1600-2300 \mathrm{~cm}^{-1}$, in clear contrast to other cumulenes such as $\mathrm{Ph}-\mathrm{N}=\mathrm{C}=\mathrm{P}-\mathrm{Ar}^{1-3}$ where strong bands were observed in the same region and usually assigned to the antisymmetrical stretching of the $-\mathrm{P}=\mathrm{C}=\mathrm{N}-$ group. Results from Table 4 indicate that there are two distinct stretching frequencies both belonging to the $C=C=P$ skeleton of (1). The first at $1987 \mathrm{~cm}^{-1}(4-31 G$ value) can be assigned to the stretching of $\mathrm{C}=\mathrm{C}$ bond and the second at $789 \mathrm{~cm}^{-1}$ to the stretching of the $\mathrm{C}=\mathrm{P}$ bond. The normal co-ordinates corresponding to these modes of vibration can be in shown in schematic form in (8) and (9).

Similar calculations ${ }^{24}$ on ketenimine (4) provide the following data in (10) and (11) for the $C=C=N$ stretching frequencies ( $4-31 \mathrm{G}$ values). After correction with a scale factor of 0.9 , the asymmetric stretching frequency (10) becomes $v_{\mathrm{CCN}}$ $2091 \mathrm{~cm}^{-1}$ and this value is in good agreement with the experimental frequency of $2040 \mathrm{~cm}^{-1}$ previously reported for $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}(1)$ in an Ar matrix. ${ }^{25}$

The difference in both molecules (1) and (4) is quite clear. No

Table 4. Harmonic vibrational frequencies (4-31G) of $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$

|  |  | Wavenumber ( $\left.\mathrm{cm}^{-1}\right)^{\text {a }}$ | Assignment |

${ }^{a}$ Values in parentheses are the predicted frequencies with an average scale factor of $v_{\text {predicted }} / v_{4-31 G}=0.9$ for the $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}$ moiety, see text.
stretching mode involving the whole $\mathrm{C}=\mathrm{C}=\mathrm{P}$ group in (1) exists, while there are two in (4), one symmetrical and one asymmetrical. In 1-phospha-allene (1), both $\mathrm{C}=\mathrm{C}$ stretching (8) and $\mathrm{C}=\mathrm{P}$ stretching (9) are nearly independent of each other. The $\mathrm{C}=\mathrm{P}$ stretching frequency of $789 \mathrm{~cm}^{-1}$ in (1) is smaller than that of $1146 \mathrm{~cm}^{-1}$ calculated for phosphaethene $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH} .^{23}$ This independence can be considered as a consequence of the noninteraction, geometric and electronic, between $\mathrm{C}=\mathrm{C}$ and $\mathrm{C}=\mathrm{P}$ bonds in the cumulated structure (1) (see above).

Interpreting this observed difference in the i.r. spectrum, Yoshifuji et al. ${ }^{3 a}$ have suggested that there is only a small contribution of the resonance form (1b) (see above) to (1). As shown above from the electric field gradients, our results more or less support this assumption. Nevertheless, this assumption appears to be not satisfactory in interpreting the behaviour of ketenimines. ${ }^{26}$ From symmetry considerations, the $\mathrm{C}=\mathrm{C}$ stretching mode (8) of (1) may be active in the Raman. Further i.r. investigations of 1 -phospha-allenes as well as comparative theoretical studies on different phosphacumulenes including the calculations of vibrational intensities (from dipole moments) are necessary in order to understand this important and interesting point.
(6) Protonation Sites and Proton Affinities.-We consider here seven possible structures of the protonated $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ : $\beta$ carbon protonation, (12) (minimum) and (13) (saddle point); $\alpha$ carbon protonation, (14), (15) (minima), and (16) (saddle point); and phosphorus protonation, (17) (minimum) and (18) (saddle point). The corresponding total energies and proton affinities calculated at different levels are listed in Tables 5 and 6, respectively.

Some points are noteworthy. (a) The ordering of the computed proton affinities (PA) is: PA $[\alpha-\mathrm{C},(14)]>\mathrm{PA}[\mathrm{P}$, (17) $]>$ PA $[\beta-C,(12)]$, and hence the $\alpha$-carbon constitutes the preferred site of protonation in 1-phospha-allene in contrast to the case of ketenimine (4) where the ordering $\left(6-31 \mathrm{G}^{* *} / / 4-31 \mathrm{G}\right)$ is $\mathrm{PA}\left(\beta-\mathrm{C}, 231.8 \mathrm{kcal} \mathrm{mol}^{-1}\right)>\mathrm{PA}\left(\mathrm{N}, 217.4 \mathrm{kcal} \mathrm{mol}^{-1}\right)>\mathrm{PA}$ $\left(\alpha-\mathrm{C}, 175.2 \mathrm{kcal} \mathrm{mol}^{-1}\right) .^{27}$ That is also different from the case of $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH}(6)$ where $P$-protonation has recently been predicted as favoured over $C$-protonation: PA ( $\mathrm{P}, 190 \mathrm{kcal}$ $\left.\mathrm{mol}^{-1}\right)>$ PA (C, $179 \mathrm{kcal} \mathrm{mol}^{-1}$, results at MP4/6-31G**). ${ }^{28}$
(b) At the MP4/6-31G** level, the calculated energy difference between (14) and (17) is $10 \mathrm{kcal} \mathrm{mol}^{-1}$ while that between (12) and (17) is only $2 \mathrm{kcal} \mathrm{mol}^{-1}$. The correlation energy tends thus to reduce the separation between protonated species. These rather small energy gaps could obviously be reduced again by substituents and, consequently, all possible protonated species could be observed. Combined with the

& \mathrm{HPC}_{1} \mathrm{C}=90^{\circ}
\end{aligned}
$$

(13)
negative contribution of the zero-point vibrational energy by $c a$. $7 \mathrm{kcal} \mathrm{mol}^{-1}$ to the PA, we can estimate a proton affinity of $193 \pm 5 \mathrm{kcal} \mathrm{mol}^{-1}$ for the $\alpha-\mathrm{C}$-site of $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$.
(c) The local minimum of the $\beta$-carbon-protonated species has a bent $E$-structure (12). The linear structure (13) is a saddle point and lies at $30 \mathrm{kcal} \mathrm{mol}^{-1}$ (DZP//4-31G) above (12). The species (12) is also the $P$-protonated $\mathrm{H}_{3} \mathrm{CC} \equiv \mathrm{P}$. At the $4-31 \mathrm{G} / / 4$ 31 G level, the corresponding PA is $159.4 \mathrm{kcal} \mathrm{mol}^{-1}$ which is larger than that of $134 \mathrm{kcal} \mathrm{mol}^{-1}$ obtained for $\mathrm{H}-\mathrm{C} \equiv \mathrm{P}^{28}$ at 3$21 \mathrm{G} / / 3-21 \mathrm{G}$. It is, however, shown that the $P$-protonation of phosphaethyne HCP is strongly disfavoured with respect to the $C$-protonated derivative by ca. $45 \mathrm{kcal} \mathrm{mol}^{-128}$ (3-21G).
(d) The cis-conformer (15) of the $\alpha$-carbon-protonated species

(19)

(20)
lies $c a .1 \mathrm{kcal} \mathrm{mol}^{-1}$ above the most stable (14). The interconversion (15) $\rightleftharpoons(14)$ via the transition structure (16) requires a barrier to rotation of $23.7 \mathrm{kcal} \mathrm{mol}^{-1}$ (DZP). Accordingly, both conformers can be observed as stable intermediates. By comparison with the couple $\mathrm{H}_{3} \mathrm{C}-\mathrm{PH}^{+} / \mathrm{H}_{2} \mathrm{C}=\mathrm{PH}_{2}{ }^{+}$(where the former lies $c a .12 \mathrm{kcal} \mathrm{mol}^{-1}$ above the latter ${ }^{28}$ ), it can be pointed out that the preferred $\alpha$-carbon site of protonation in 1 -phospha-allene (1) arises from the stabilizing effect of the vinyl group ( $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}-\mathrm{PH}^{+} / \mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}_{2}{ }^{+}$: the former lies $10-12 \mathrm{kcal} \mathrm{mol}^{-1}$ below the latter). Populating the vacant orbital of the P atom in the phosphenium cations $\left(\mathrm{R}_{2} \mathrm{P}^{+}\right)$by electrons from $\pi$-donor substituents should in fact stabilize them considerably. Experimentally, several diaminophosphenium cations $\left(\mathrm{R}_{2} \mathrm{~N}\right)_{2} \mathrm{P}^{+}$, have been prepared and they undergo cycloadditions, for example, like carbenes or silylenes. ${ }^{29.30}$

(21)

(22)

(23)

(24)
(7) Chemical Reactivity.-No experimental facts have been reported as yet on the chemical reactivity of 1-phospha-allenes. We attempt to predict here their reactivity and to compare them with those of ketenimines which are well established. First, it is useful to analyse the HOMOs and the LUMOs of both $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PH}$ (1) and $\mathrm{H}_{2} \mathrm{C}=\mathrm{C}=\mathrm{NH}$ (4). They are schematized in (19) and (20), respectively. In (1), both HOMO and LUMO [see (19)] appear to be dominated by the $\mathrm{C}=\mathrm{P}$ bond which possesses the largest orbital coefficients, whereas both $\mathrm{C}=\mathrm{C}$ and $\mathrm{C}=\mathrm{N}$ bonds in (4) have comparable MO coefficients. The picture of the CP moiety in (19) is very similar to that in $\mathrm{H}_{2} \mathrm{C}=\mathrm{PH} .{ }^{6}$
(a) Addition to $H X$. Without a catalyst, the nucleophile part $\left(\mathrm{X}^{-}\right.$) of proton-acidic reagents HX can be predicted to add to the P atom; this is followed by a proton transfer to the $\alpha-\mathrm{C}$ atom [equation (1)] within a concerted mechanism. With acidic

$$
\begin{equation*}
\mathrm{R}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PR}+\mathrm{HX} \longrightarrow \mathrm{R}_{2} \mathrm{C}=\mathrm{CH}-\mathrm{PRX} \tag{1}
\end{equation*}
$$

catalysis, the $x$-C-site protonation occurs first and the anionic nucleophile $\mathrm{X}^{-}$adds to the phosphenium cation subsequently [equation (2)]. In both cases, the vinylphosphines will be

$$
\begin{align*}
\mathrm{R}_{2} \mathrm{C}=\mathrm{C}=\mathrm{PR}+\mathrm{H}^{+} \longrightarrow \mathrm{R}_{2} \mathrm{C}=\mathrm{CH}-\mathrm{PR}^{+} \xrightarrow[\mathrm{R}_{2} \mathrm{C}=\mathrm{CH}-\mathrm{PRX}]{\mathrm{X}}
\end{align*}
$$

obtained as primary adducts. Note that for ketinimines, ${ }^{26}$ phosphaketenes $\mathrm{RP}=\mathrm{C}=\mathrm{O},{ }^{4}$ and carboimidophosphenes $\mathrm{RN}=\mathrm{C}=\mathrm{PR},{ }^{1-3}$ the $\alpha$-carbons are electrophilic and are attacked by nucleophile to form azomethine or carbonyl derivatives in the first step.
(b) Cycloadditions. The dimerization of 1-phospha-allene can be expected to occur as a head-to-tail addition of two $\mathrm{C}=\mathrm{P}$ moieties, leading to diphosphetane (21). This cycloadduct is usually obtained from 1,1 -self-condensation of phospha-alkenes or phosphacumulenes. ${ }^{1-6}$ Condensation of (1) to a polar multiple bond $\stackrel{+}{\mathrm{X}}=\overline{\mathrm{Y}}$ such as $\mathrm{C}=\mathrm{N}$ in carbodi-imides or isocyanates could also be predicted to generate the fourmembered ring (22) rather than (23). As a matter of fact, both charge and orbital considerations act in favour (22).

Concerning 1,3-dipolar cycloaddition of 1-phospha-allene with diazomethane, for example, the five-membered ring (24) is predicted to be the adduct of the normal addition.
