

## Conformational Studies of Substituted Five-membered Cyclic Carbonates and Related Compounds by MNDO, and the X-Ray Crystal Structure of 4-Chlorophenyloxymethyl-1,3-dioxolan-2-one

Jehoshua Katzhendler,<sup>a</sup> Israel Ringel,<sup>b</sup> Amiram Goldblum,<sup>a</sup> Dan Gibson,<sup>a</sup> Zeev Tashma<sup>a</sup>  
 Departments of Pharmaceutical Chemistry<sup>a</sup> and Pharmacology<sup>b</sup> School of Pharmacy, The Hebrew University of Jerusalem, Israel

Geometries, torsional barriers, and dipole moments have been computed for mono-, di-, tri-, and tetra-substituted five-membered cyclic carbonates and for some substituted cyclopentanones, oxolanes, 4-butyrolactones, and 1,3-dioxolanes. With respect to cyclic carbonates it was deduced that the potential curve increases moderately with  $T_{3456}$  (torsion angle) and for most compounds a 1 kcal difference between  ${}^4T_5$  or  ${}^5T_4$  conformers and planar form corresponds to a torsional angle of  $\pm 14$ – $16^\circ$ . The minimum is, in general, flattened and close to planar. Additional modes of ring puckering such as  ${}^5E$ ,  $E_5$ ,  ${}^4E$ ,  $E_4$  and  ${}^2E$ ,  $E_2$  were also examined. Between the enantiomeric structures with opposite distortions, the quasi equatorial conformation of the alkyl group is preferred.

*endo* and *exo* anomeric effects in carbonate systems have been studied by introducing strong electron-withdrawing substituents, in the carbonate 4-position. The *exo* anomeric effect was observed with many of the polar substituents, but the role of the anomeric effect in ring puckering (*endo* effect) was found to be small.

For other five-membered ring systems MNDO predicts that the energy barrier to interconversion of planar  $\longleftrightarrow$  twist is in the following order: carbonates > 1,3-dioxolanes > butyrolactones > oxolanes > cyclopentanones.

N.m.r. data are also included as well as the single-crystal X-ray diffraction study of 4-chlorophenyloxymethyl-1,3-dioxolan-2-one.

It is well documented and widely accepted that five-membered ring systems and cyclopentane exist in a continuous pseudorotation<sup>1,2</sup> mobility between 20 isoenergetic extreme conformations  $C_s$  (envelope or bent) and  $C_2$  (half chair or twisted). The presence of substituents, or the inclusion of endocyclic or exocyclic heteroatoms in the ring is known to restrict the equilibrium by changing the torsion potential barriers of the pseudorotation circuit.<sup>1d,3-7</sup> It was predicted<sup>1c</sup> that substituents which increase the torsional barrier around the C–C bond favoured a  $C_s$  conformation while  $C_2$  is preferred in cases of decreased rotational barriers. Thus, methyl substitution favours  $C_s$  conformation<sup>1d,8,9</sup> (with an inversion barrier of  $\sim 0.9$  kcal mol<sup>-1</sup>)<sup>†</sup> while cyclopentanone has been shown to prefer the  $C_2$  conformation.<sup>1d,10,11</sup> Oxolane<sup>2d,10</sup> and 1,3-dioxolane<sup>10</sup> were also predicted to restrict the pseudorotational motion while preferring the  $C_2$  conformation. 2-Oxo-1,3-dioxolane, exists in the crystal<sup>12</sup> form in a half-chair conformation with the torsional angle O–C(4)–C(5)–O being  $31^\circ$ . N.m.r. data based on  ${}^1H$  and  ${}^{13}C$  chemical shifts and  ${}^1H$  vicinal coupling constants are also in accord with this view.<sup>13</sup> On the other hand some of the results indicate a non-planar ( $C_{2v}$  symmetry) structure for ethylene carbonate.

In order to gain further insight into the conformational changes in the 2-oxo-1,3-dioxolane ring (ethylene carbonate), we have studied some substituted ethylene carbonates and iminocarbonates by n.m.r. spectroscopy, single-crystal X-ray diffraction studies and semiempirical MNDO calculations. The structure of the compounds studied is given in Table 1.

For comparison we also studied the conformational modes

of some substituted cyclopentanone, oxolanes, 4-butyrolactones, and 1,3-dioxolanes (Table 2).

### Results and Discussion

<sup>13</sup>C N.M.R. Long-range Coupling.—The generally accepted approaches to conformational analysis by n.m.r. spectroscopy consist of  ${}^1H$  and  ${}^{13}C$  chemical shifts, vicinal ( $R$  values) and long range ( ${}^3J$ ) coupling, and anisotropic effects of the substituents. Some of these methods have been used in the past for conformational assignment of the 2-oxodioxolane ring. The results strongly support the existence of a non-planar structure. The  ${}^3J$  coupling between the protons on C-4 (or C-5) of the carbonate ring with  ${}^{13}C=O$  ( ${}^1H-C-O-{}^{13}C=O$ ) can also contribute to the evaluation of ring conformation.

Substituents on the carbonate ring might change the torsional angles and thus affect the  ${}^3J$  coupling constant. Table 3 displays the long range coupling constants of ethylene carbonate derivatives;  ${}^3J = 3.1$  Hz for ethylene carbonate, is a time-averaged value of rapidly interconverting conformers. The *meso*-4,5-dimethyl isomer *c*-(**2c**) exhibits a  ${}^3J$  value of 2.9 Hz which is similar to that of ethylene carbonate (digital resolution is *ca.* 0.2 Hz per point), so that a methyl substituent does not change the  ${}^3J$  value.

The spectrum of  ${}^{13}C=O$  coupled by the ring protons of *t*-4,5-dimethylethylene carbonate [*t*-(**2a**)] appears as a triplet with  ${}^3J = 2.2$  Hz. This low value can be attributed mainly to the changes in the torsional angles, probably due to a quasiequatorial and quasiallial orientation of the methyl groups and ring hydrogens, respectively.

The coupled  ${}^{13}C=O$  spectrum of 4-methylethylene carbonate displays two triplet signals (Figure 1) with  ${}^3J$  values of 2.7 and

<sup>†</sup> 1 cal = 4.184 J.

<sup>a</sup> (1), (2), (3), and (4) denote mono-, di-, tri-, and tetra-substitution. The abbreviations *t*, *c*, and *g* correspond to *trans*, *cis*, and *gem* configuration.

<sup>b</sup> We decided to adopt the above notation to represent the numbering scheme for all the different groups of heterocyclic compound irrespective of their systematic nomenclature (*i.e.* 1,3-dioxolane has the oxygen atoms at positions 3 and 6). <sup>c</sup> *Z* and *E* denote *Z* and *E* configurations.

3.4 Hz. These values indicate again a non-planar conformation of the ring skeleton.

**MNDO Calculations.**—In order to predict the preferred conformations of substituted 1,3-dioxolan-2-ones and of some other five-membered ring systems, MNDO semiempirical SCF calculations were carried out. All the geometrical parameters were fully optimized. Tables 4–6 summarize the theoretical bond lengths, bond angles, and torsion angles of the compounds in their optimized geometry. These tables present geometries and energy values which were calculated for the various

compounds studied. Error estimates of quantum-mechanical values are dependent on the gradient convergence precision and are, in our calculations, about  $\pm 0.0001$  Å for bond lengths. However, the values for bond lengths and angles and values of enthalpies (precision of  $\pm 0.0002$  kcal mol<sup>-1</sup>) must be compared with experiments which are less precise. Thus we present values of lower significance than the calculated precision. Table 4 presents the results for cyclopentanone, oxolane, 1,3-dioxolane, 4-butyrolactone, 2-oxo-1,3-dioxolane and for their monomethyl derivatives.

Cyclopentanone was calculated to be most stable in the planar conformation (Table 4). Its 2-methyl derivative (5b) is also planar, while 3-methylcyclopentanone (5a) has a discrete minimum in the C<sub>2</sub> form. In contrast with the reported data in the literature<sup>10a,14</sup> the calculated degree of puckering of the molecule is low ( $T_{3456} = 14.0^\circ$  ( $T$  = torsional angle) compared with a reported value of 39–40°).

In the case of oxolanes, MNDO calculations predict a planar structure for the non-substituted compound and for its 2-methyl derivative, and a very small degree of puckering ( $T_{3456} = 4.3^\circ$ ) for the 3-methyloxolane. These results are inconsistent with pseudorotation assignments for furanose<sup>15–17</sup> rings and with previous<sup>10a</sup> quantum-mechanical data calculated for oxolane which indicate a preference for a C<sub>2</sub> conformation by 2.6 kcal over the planar form. Further MNDO calculations on 1,3-dioxolanes and 4-butyrolactones (Table 4) were in accord with a planar conformation. Although endocyclic or exocyclic hetero atom in a five-membered ring system imposes

additional forces on the ring, non-planar conformations and ring-conformer interconversions of 1,3-dioxolanes<sup>10a</sup> and 4-butyrolactones<sup>18–20</sup> are well recognized.

Recently, crystallographic data of 1,3-dioxolanes<sup>21,22</sup> have demonstrated a twist angle in the range  $T_{3456} = 28\text{--}37^\circ$ . *ab initio* molecular-orbital (MO) calculations (4-31G basis set) for 1,3-dioxolane showed an energy difference of 1.4 kcal between the planar (least stable) and the  $C_2$  conformer.<sup>10b</sup> For 4-butyrolactone<sup>18</sup> the energy difference between conformers is again *ca.* 0–1.3 kcal.

In contrast with the above results the MNDO calculations presented here predict the planar conformation as the most stable form. However it is possible from these calculations to evaluate the tendency of a five-membered ring system to undergo ring deformation.

Table 7 presents the  $\Delta H_f$  values of five-membered ring systems and their monomethyl derivatives at different  $T_{3456}$  angles (cyclopentanones (5)–(5b), oxolanes (6)–(6b), 1,3-dioxolanes (7)–(7b), 4-butyrolactones (8)–(8c) and 2-oxo-1,3-dioxolanes [(1), (1a)]. It appears that cyclopentanone possesses the greatest tendency for deformation. The energy barrier between the planar form and  $C_2$  at  $T_{3456} = 20^\circ$  is *ca.* 0–0.2 kcal in the monomethyl derivatives and 0.4 kcal in cyclopentanone. A further increase in the torsional angle to  $30^\circ$  increases the energy barrier ( $\Delta\Delta H_f$ ) to 0.95, 0.56, and 1.35 kcal for (5b), (5a), and (5), respectively. According to the Boltzman weighting equation<sup>24</sup> a 1 kcal difference decreases the population of the less stable conformer to *ca.* 15%. The calculations indicate that among the substituted compounds: (a) two enantiomeric structures with opposite distortion (negative and positive torsional

**Table 6.** Geometric parameters of substituted 2-oxo-1,3-dioxolanes produced from MNDO calculations. Crystallographic data are according to the following notation.

<sup>a</sup> *R*<sub>4,7</sub> = 1.565 (1.534); *R*<sub>7,8</sub> = 1.404 (1.431); *R*<sub>8,9</sub> = 1.3712 (1.381);  $\theta_{7,43}$  = 111.5 [108.5(4)];  $\theta_{8,74}$  = 109.1 [108.6(4)];  $\theta_{9,87}$  = 119.9 (115.6); *T*<sub>7432</sub> = –124.1 [–121.7(4)]; *T*<sub>8743</sub> = –70.9 [65.0(4)]; *T*<sub>9874</sub> = 144.3 [–169.1(3)]; *T*<sub>10987</sub> = –106 [176.9(3)]. <sup>b</sup> Estimated standard deviations are in parentheses.

angles) do not exhibit equal energy. The preferred form in general corresponds to a positive value where the methyl group adopts a quasi-equatorial conformation, and (b) ring substitution by a methyl group decreases (at least for one of the enantiomers) the interconversion energy barrier (except for ethylene carbonate).

In the case of oxolanes (**6a, b**) and 4-butyrolactones (**8a–c**), the energy barrier between the planar and the stable conformer at 20° distortion is less than 1 kcal. This difference permits a significant amount of the *C*<sub>2</sub> conformers to exist. In the case of 1,3-dioxolanes and 2-oxo-1,3-dioxolanes, the respective barriers have higher enthalpy values. It seems therefore that in comparison with other five-membered ring systems the presence of two endocyclic oxygens, restricts ring puckering. The energy barriers order in the planar ↔ twist interconversion in the above ring systems is carbonates > 1,3-dioxolanes > butyrolactones > oxolanes > cyclopentanones.

Crystallographic data of non-substituted 2-oxo-1,3-dioxolane and of the compound substituted with strong electron-withdrawing groups such as 4,5-bis-fluorodinitromethyl<sup>23</sup> show a non-planar structure with *T*<sub>3456</sub> = 28–31°. In contrast

with these results the crystal structure of 4-chlorophenylloxymethyl-1,3-dioxolan-2-one (**1h**) displayed a virtually planar conformation. Values of geometric parameters from crystal-structure and MNDO calculations are given in Table 6.

In general there is a good correlation between the computed and the measured bond lengths, bond angles, and dihedral angles. However, several differences were observed: (a) the backbone conformation according to computation is planar while a ring deformation of –3.40(5) is observed in the crystal structure; (b) the oxygen bond angles in the side chain differ by 4.2°; (c) the oxygen torsional angle *T*<sub>8743</sub> according to MNDO calculations is –70.9°, however, from the crystal data the corresponding value is +65.0° (4); (d) the phenyl ring in the crystal deviates by 3.1(3)° from the plane of atoms 7–8–9 while the computed value yields a rotation of 74°. In addition some differences in *R*[C(4)–C(5)] and  $\theta(2, 3, 4)$  are also found.

MNDO conformational-energy calculations of (**1**), (**1a**), and (**1h**) show a preference for a planar conformation. In order to assess the contributions of electronic and steric effects we

extended the calculations to various types of polar substituents and to polymethyl substituents. The results are presented in Tables 5 and 6. It can be seen that with respect to *c*-(2a), *t*-(2a), and *g*-(2a) dimethyl substituents, only the *trans* isomer experiences slightly increased ring distortion ( $T_{3456} = 1.80^\circ$ ). With dichlorosubstituents *t*-(2c), *c*-(2c), and *g*-(2c) the *trans* isomer again experienced the most ring deformation ( $T_{3456} = -6.30$ ). However, with  $\text{OCH}_3$  (*t*-(2b) and *c*-(2b) both *cis* and *trans* isomers exhibited a small degree of ring puckering.  $\text{CF}_3$  did not exert any significant effect on the planar form, although a bulky substituent such as  $\text{CCl}_3$  appears to bring about considerable conformational changes.

Steric hindrance and polar repulsive interactions between these substituents in the *cis* position *c*-(2e) imposes a relatively high degree of ring distortion ( $T_{3456} = 13.6^\circ$ ). The *trans* isomer *t*-(2e) experiences a moderate effect similar to that felt by Cl *t*-(2c) ( $T_{3456} = 6.3^\circ$ ). In all cases the effect of *gem*-dialkyl groups on the ring conformation was negligible.

Comparison between the torsional angles (Tables 5, 6) in mono- and di-substituted carbonates [(1c), *t*-(2c); (1b), *t*-(2b)] suggests that substituent effect on  $T_{3456}$  is additive [ $3^\circ$  vs.  $6.2^\circ$  and  $2.9^\circ$  vs.  $4.9^\circ$  in (1c), *t*-(2c), and (1b), *t*-(2b), respectively].

The  $T_{3456}$  value of the 2,2,3-trimethyl derivative of ethylene carbonate (3) and the 2,2,3,3-tetramethyl derivative of ethylene carbonate (4) is close to zero. Since puckering of the latter compound does not seem to relieve steric strain, the data

indicates that the reduction of strain occurs *via* the increase in  $R_{45}$  bond length up to 1.630 Å.

The 'anomeric effect' is a well recognized phenomenon<sup>25,26</sup> related to the tendency of electronegative substituents at anomeric carbon in pyranose rings to prefer an axial position to an equatorial one. It was first interpreted in terms of dipole-dipole interaction and latter by the  $n \rightarrow \sigma^*$  electron donation from oxygen lone pair to the antibonding C-O orbital of an adjacent C-O bond.

This type of stabilization is expected to lead to a preference for a *gauche* conformation for atoms 2, 3, 4, 5 ( $T_{\text{endo}}$  ca.  $60^\circ$ ). If  $\text{X} = \text{O}$  (or any other electronegative atom) an *exo* anomeric effect in atoms 3, 4, 7, 8 is also expected ( $T_{\text{exo}}$  ca.  $60^\circ$ ).

The more electronegative the X substituent is, the lower the corresponding  $\sigma^*$  (C-X) orbital (*i.e.* an increase in acceptor properties). Lowering of the  $\sigma^*$  orbital can also be achieved by increasing the electronegativity of Y. On the other hand, an electron-donating substituent on C(2) is expected to increase the oxygen lone-pair orbital level and its donation properties. These two parameters seem to enhance the anomeric effect.

In cyclic carbonates, the carbonyl on C(2) reduces the availability of the  $n_o$  lone pair electrons on O(3) to overlap with orbitals of C(4). It is conceivable, however, that replacing X or Y by strong electron-withdrawing substituents will enhance conformational changes due to the anomeric effects.

Table 8 summarizes the torsion angles ( $T_{\text{endo}}$  and  $T_{\text{exo}}$ ) for several cyclic carbonates substituted at C(4) with strong electron-withdrawing groups. From the data it is inferred that the ring is approximately planar and that group X adopts a bisecting position with  $T_{\text{endo}}$  111–128°. In addition, almost all polar groups in Y are oriented in a *gauche* conformation ( $T_{\text{exo}} = 60$ – $100^\circ$ ) except for Cl.

In 4,5-disubstituted ethylene carbonate  $T_{\text{exo}}$  for *trans*-4,5-dimethoxy groups are -82.2 and 81.9°. For the *cis* isomer the corresponding values are -85.7 and 31.2° and for the *gem*-dimethoxy isomers the  $T_{\text{exo}}$  values are 68.8 and 17.3°. These results indicate that when a disubstituted compound is sterically hindered, at least one of its alkoxy groups adopts a *gauche* conformation. It is also noteworthy (Table 8) that  $\text{CH}_2\text{Cl}$  and  $\text{CH}_2\text{F}$  do not display similar  $T_{\text{exo}}$  values in their optimized structures. Table 9 presents additional data calculated by MNDO for the rotation around C(4)-X(7) bond ( $T_{\text{exo}}$ ). It appears that both  $\Delta H_f$  and  $T_{\text{endo}}$  depend on  $T_{\text{exo}}$  values. The

Figure 2. The effect of ring torsion ( $T_{3456}$ ) in substituted ethylene carbonates on  $\Delta H_f$ .

Figure 3. Energy barrier  $\Delta H_f$  in (1b) due to changes on  $T_{3456}$ : (a)  $T_{3456}$  calculated with no constraints; (b)  $T_{3456}$  calculated under the constraint  $T_{1234} = 180^\circ$ .

maximal changes in  $\Delta H_f$  due to rotation around the C(3)-X(4) bond is 4.4, 2.9, and 6.0 kcal for  $\text{CH}_2\text{Cl}$ ,  $\text{CH}_2\text{F}$ , and  $\text{OCH}_3$ , respectively. In the case of  $\text{CH}_2\text{Cl}$  and  $\text{CH}_2\text{F}$ , rotation of the polar groups Cl and F in  $\text{O}-\text{C}-\text{C}-\text{X}$  ( $\text{X} = \text{Cl}, \text{F}$ ) from the eclipsed conformation ( $T_{exo} = 0$ ) to higher dihedral angles gives rise to a constant increase in  $T_{endo}$  up to a maximum of  $T_{exo} =$

$120-150^\circ$ . A further rotation decreases  $T_{endo}$  values. Ring puckering ( $T_{2345}$ ) increases accordingly with a maximal value at  $T_{exo} = 150^\circ$ .

It is also noticeable that (a) the conformation of the molecule related to the maximum does not coincide with the most stable form which occurs at  $T_{exo} = 58.1$  and  $180^\circ$  for F and Cl, respectively and (b) the trend in  $T_{exo}$  is not reflected by the total change in dipole moment. On the other hand,  $T_{endo}$  seems to correlate with the  $R_{34}$  bond length. The increase of puckering toward a pseudo-axial position of a substituent is accompanied by a lengthening of the  $R_{34}$  bond. Although the displayed correlation deals with small effects, the tendency of this relationship is not in accordance with the anomeric effect where an  $\text{O}-\text{CH}_2$  bond in  $\text{C}-\text{O}-\text{CH}_2\text{CH}_2\text{X}$  is expected to shorten.

In the case where X-Y in  $\text{C}(2)-\text{O}(3)-\text{C}(4)-\text{X}(7)-\text{Y}(8)$  is  $\text{OCH}_3$ ,  $T_{exo}$  operates in an opposite direction. An increase in  $T_{exo}$  decreases  $T_{endo}$  until a minimum is reached at  $T_{exo} = -90^\circ$  (for  $T_{2345}$  the minimum is at  $-150^\circ$ ). This is probably due to the opposite direction of the  $\text{C}-\text{O}-\text{C}$  dipole moment vector compared with that of  $\text{CH}_2-\text{X}$  at any torsional angle. In this case the conformation of the molecule at the minimum is very close to the most stable conformation. However in contrast with the above, the tendency of ring puckering is toward a quasi-equatorial substituent position rather than a quasi-axial position. Since the  $R_{43}$  bond length values are scattered, no correlation can be made.

From these models ( $\text{CH}_2\text{X}$ ,  $\text{CH}_2\text{OCH}_3$ ), it seems that steric factors might also be operative and have to be taken into consideration. In general it can be said that the role of the anomeric effect in ring puckering of ethylene carbonate is small. The potential barriers of ring puckering *via* variation of torsional angles  $T_{3456}$  are given in Table 8 and in Figure 2.

From the data it is inferred that the potential curves incline moderately and for most of the compounds a 1 kcal difference between  ${}^4T_5$  or  ${}^5T_4$  conformers and the planar form corresponds to a torsional angle of  $\pm 14-16^\circ$ . In the case of (4) (tetramethyl derivative) the minimum is less curved and a torsional angle of  $\pm 20^\circ$  increases  $\Delta H_f$  by only 0.63 kcal.

By analogy with (1a),  ${}^4T_5$  conformers in (1e), (1f), and (1h) are more stable than their  ${}^5T_4$  enantiomers (the substituents are in quasi-equatorial orientations). However, in the case of (1d),  ${}^5T_4$  is the most stable one. It was also noted that with dimethyl substituents [*t*-, *c*-, and *g*-(2a)] the *gem*-dialkyl isomer *g*-(2a) is more resistant to ring torsion than the *trans*- or the *cis*-(2a) isomers.

The energy barriers of the compounds (2a) are identical and no preference for either  ${}^4T_5$  or  ${}^5T_4$  conformers was observed. In addition to  ${}^4T_5$  and  ${}^5T_4$  conformers, we considered some additional modes. Figure 3 presents energy barriers ( $\Delta H_f$ ) for two modes of variable dihedral angles of (1a). Case (a) corresponds to the change of  $T_{3456}$  with no constraints on other backbone dihedral angles. Case (b) refers to  $T_{3456}$  twisted angles with  $T_{1234}$  fixed at  $180^\circ$ . The latter allows the formation of slightly deformed  ${}^5E$  and  $E_5$  conformers, in which O(6) is out of the  $\text{O}-\text{C}-\text{O}$  plane in the direction of C(5) with  $q(6)=0.15q(5)$  ( $q$  is the displacement in the  $z$  direction, and corresponds to the puckering amplitude in a pseudorotation circuit). It can be seen (Figure 3) that the twisted form of case (a) is slightly more stable than that of case (b), particularly at high degrees of puckering.

Other types of ring puckering were obtained according to the following operations (Figure 4): (a) case (c), twisting about the  $\text{C}(5)-\text{C}(6)$  bond ( $T_{2654}$ ), (b) case (i), twisting of  $\text{C}(3)-\text{C}(4)$  bond ( $T_{2345}$ ), (c) case (b), twisting at the  $\text{C}(3)-\text{C}(4)$  bond with  $T_{1234}$  fixed at  $180^\circ$ , (d) case (j), twisting at the  $\text{C}(5)-\text{C}(6)$  bond with  $T_{1265} = 180^\circ$ , and (e) case (f), twisting at the  $\text{C}(3)-\text{C}(4)$  bond with  $T_{3456} = 0^\circ$ . Cases (c) and (i) result in slightly deformed ( ${}^5E$ ,  $E_5$ ) and ( ${}^4E$ ,  $E_4$ ) envelope forms, respectively, while case (f)

**Figure 4.** The effect of various modes of twisted angle ( $T$ ) in IB on  $\Delta H_f$ . (c)  $T_{3456}$ ; (i)  $T_{2345}$ ; (b)  $T_{2345}$  while  $T_{1234} = 180^\circ$ ; (j)  $T_{4562}$  while  $T_{1265} = 180^\circ$ ; (f)  $T_{2345}$  while  $T_{3456} = 0^\circ$ .

**Table 10.**  $\Delta H_f$  values of substituted cyclic carbonates and iminocarbonates of planar and twisted forms.

$T_{3456}$ Comp.	$\Delta H_f/\text{kcal}$

(1f)	-119.44	-119.02 -119.06	-117.74 -117.70	-115.17 -114.92
(1h)	-142.93	-142.60 -142.46	-141.35 -141.03	-138.85 -138.25
<i>Z</i> -(1a)	-48.90	-48.57 -48.42	-47.44 -47.11	-45.10 -44.50
<i>E</i> -(1a)	-48.89	-48.59 -48.45	-47.44 -47.13	-45.10 -44.55
<i>Z</i> -(1g)	-14.04	-13.49	-12.00	9.87(28°)

corresponds to the ( ${}^2E$ ,  $E_2$ ) form. Case (b) results in a significantly deformed envelope conformation where C(2), O(3), and C(4) residue in the same plane while C(5) and O(6) are out of plane in the same direction. The displacement of O(6) is *ca.* 0.45 of  $qC(5)$ . Case (j) resembles 2A with C(2), O(6), and C(5) in plane. The displacement of O(3) in the  $z$  direction is  $q^3 = 0.45q^4$ . It can be seen that the energy barrier in  ${}^5E$ ,  $E_5$ ,  ${}^4E$ ,  $E_4$

[cases, (c) and (i)] conformers is lower than in the other envelope forms. A change of *ca.*  $13^\circ$  in  $T_{2654}$  [case (c)] or in  $T_{2345}$  [case (i)] corresponds to *ca.* 0.6 kcal only.

The present study also includes calculations on some iminocarbonates *Z*- and *E*-(1a) and *Z*-(1g). From Table 10 it is deduced that five-membered ring cyclic carbonates and five-membered ring iminocarbonates have similar energy barriers to conformer interconversions. By analogy with the mono-substituted carbonates twisting of the iminocarbonates by  $T_{3456} = 14\text{--}16^\circ$  gives rise to  $H_f$  of *ca.* 1 kcal. No significant difference between the *E* and *Z* conformers was observed. In the planar conformation the phenyl group rotates out of the O-C-O plane of *Z*-(1a) and *Z*-(1g) by  $82.1$  and  $78.7^\circ$ , respectively.

### Experimental

**N.M.R. Spectroscopy.**—Samples for N.M.R. measurement were dissolved in  $\text{CDCl}_3$  and examined at  $20^\circ\text{C}$  on a Bruker 200 MHz spectrometer.  ${}^{13}\text{C}$  spectra were examined with broadband decoupling of the  ${}^1\text{H}$  region. For  ${}^{13}\text{C}$  coupling constants studies, gated  ${}^1\text{H}$  decoupling was employed. When  ${}^3\text{J}$  coupling, of the  ${}^{13}\text{C}=\text{O}$  by the cyclic carbonate ring protons, was studied, narrow spectrum widths were examined to achieve a computer resolution better than 0.2 Hz per point.

**Heat of Formation ( $\Delta H_f$ ).**—Semiempirical SCF calculations were carried out using MNDO.<sup>27</sup> Total geometry optimization, including internal rotations, was applied to each of the molecular species. Second derivatives were estimated for all  $3N - 6$  geometrical parameters during optimization. The minima were verified through the second derivatives (Hessian) matrix eigenvalues, which must be all positive.

DFP<sup>28</sup> analytical gradients were used throughout the optimization. Entropies were calculated by evaluation of the vibrational, rotational, and translational partition functions.<sup>29</sup> As small differences were found between the entropies in each transformation scheme, these values are not reported.

<sup>a</sup> Estimated standard deviations in the least significant digits are shown in parentheses.

**Figure 5.** Structure of (1h) showing the 50% probability thermal ellipsoids and atom-labelling scheme.

**Crystallizations.**—X-Ray quality crystals were obtained by recrystallization of (1h) from a mixture of light petroleum- diethyl ether and ether.

**Data Collection and Processing.**—The crystals were glued onto glass fibre using epoxy resin. The data were collected on an Enraf-Nonius CAD-4F automated diffractometer with monochromatised Cu-K<sub>α</sub> (λ = 1.5418 Å) radiation. Unit-cell parameters were obtained by a least-squares fit of 20 high-angle reflections. The crystal system was found to be monoclinic and the space group was determined to be P2<sub>1</sub>/c (C<sub>25</sub><sup>5</sup>, No. 14)<sup>30</sup> from the systematic absences and, ultimately, from the solution and successful refinement of the structure. The data were collected in the θ-2θ scan mode. Lorentz and polarization corrections were applied. The intensities of the 3 standard reflections did not exhibit any decay and no correction was applied. No absorption correction was applied. Other information pertinent to data collection and processing is given in Table 11.

**Structure Analysis and Refinement.**—The solution to the structure was obtained with the aid of the direct methods program MULTAN.<sup>31</sup> The atomic positions of the chlorine and oxygen atoms were introduced and refined and the positions of the remaining non-hydrogen atoms were obtained from subsequent refinements and difference Fourier Maps.

Anisotropic thermal parameters were used for the chlorine, oxygen and carbon atoms. The hydrogen atoms were constrained to 'ride' on the carbon atoms and the aromatic hydrogens were refined with a common thermal parameter as were the aliphatic hydrogen atoms.

Using SHELX-76,<sup>32</sup> full-matrix least-squares refinements were carried out. Using unit weights, the refinement converged to satisfactory discrepancy indices which are listed in Table 11.

Final non-hydrogen positional parameters, together with their estimated standard deviations appear in Table 12. Selected interatomic distances, bond angles, and torsion angles, together with their standard deviations appear in Table 6. Figure 5 depicts the molecular geometry and labelling scheme for 4-chlorophenoxymethyl-1,3-dioxolan-2-one. The thermal parameter of the non-hydrogen atoms and the positional and thermal parameters of the hydrogen atoms have been deposited at the Cambridge Crystallographic Data Centre.\*
