# FTIR Spectral Study of Double Cyclic Intermolecular Hydrogen Bonding in Glutaric Acids 

Mamoru Takasuka,* Takashi Saito and Masumi Yamakawa<br>Shionogi Research Laboratories, Shionogi and Co., Ltd., Fukushima-ku, Osaka 553, Japan

#### Abstract

The concentration dependence of the FTIR spectra of glutaric acid 1,3-methylglutaric acid 2 and 3,3-dimethylglutaric acid 3 has been measured in $\mathrm{CCl}_{4}$ solution. In these compounds, double cyclic intermolecular hydrogen-bonded dimers involving a 16 -membered ring are formed between the molecules, in which the two carboxy groups are approximately in parallel alignment with each other. The percentage ( $h$ ) of these dimers at $3 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$ in dilute $\mathrm{CCl}_{4}$ solution has high values of $73 \%$ for $1,85 \%$ for 2 and $44 \%$ for 3 . The association constant is $7.7 \times 10^{4} \mathrm{dm}^{3} \mathrm{~mol}^{-1}$ for 2. Conformational analysis of compound 1 has been carried out by the ab initio MO method at the 3-21G(*) level.

Many IR spectral studies ${ }^{1.2}$ have been reported on cyclic intermolecular hydrogen bonds Ia in alkanecarboxylic acids in $\mathrm{CCl}_{4}$ solution, but not in $\omega$-alkanedicarboxylic acids. It has also been reported ${ }^{3}$ that $\alpha$-keto- and $\alpha$-alkoxy-carboxylic acids in $\mathrm{CCl}_{4}$ solution form intramolecular hydrogen bonds, but compounds where the substituent is further away do not. For the thromboxane $\mathrm{A}_{2}$ receptor agonist, antagonist and antagonist S-145 chain-analogues $\left[\mathrm{PhSO}_{2} \mathrm{NH}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{CO}_{2} \mathrm{H}(n=\right.$ $6-8,10$ and 11)], rings of more than nine members formed by intramolecular hydrogen bonds were found between the carboxy and amide functional groups. ${ }^{2,4-6}$

We have taken an interest in $\omega$-alkanedicarboxylic acids $\mathrm{HO}_{2} \mathrm{C}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{CO}_{2} \mathrm{H}(n=3-14)$, which can form intermolecular hydrogen bonds Ib, IIa and IIb and intramolecular hydrogen bonds IIIa-IVc, where $\tau$ is the torsion angle $\mathrm{O}=\mathrm{C}-\mathrm{O}-\mathrm{H}$ of the carboxy groups and the suffixes 1 and 2 show the left and right carboxy groups, respectively. Therefore, we first obtained FTIR spectra for glutaric acid $(n=3)$ 1, 3-methylglutaric acid [ $\left.\mathrm{HO}_{2} \mathrm{CCH}_{2} \mathrm{CH}\left(\mathrm{CH}_{3}\right) \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{H}\right] 2$ and 3,3-dimethylglutaric acid $\left[\mathrm{HO}_{2} \mathrm{CCH}_{2} \mathrm{C}\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{H}\right] 3$ in dilute $\mathrm{CCl}_{4}$ solution, in order to elucidate their hydrogen-bonded structure. The concentration dependence of the FTIR spectra of $1-3$ was also measured. Full optimization curve analysis was applied to all spectra. The results observed for $\omega$-alkanedicarboxylic acids ( $n=4-14$ ) will be reported in a separate paper. ${ }^{7}$ To aid the determination of the hydrogen-bonded structure of 1 , its conformers were optimized by the ab initio MO method at the 3-21G(*) level. ${ }^{8}$

## Experimental

Compounds 1-3 were obtained from a commercial source and purified by recrystallization. FTIR spectra were recorded on a Nicolet 20 SXB FTIR spectrometer at $27^{\circ} \mathrm{C}$. Purification of $\mathrm{CCl}_{4}$, operation for solution, and curve fitting calculation for peak separation were as previously described. ${ }^{2}$ In Table $1, v, \varepsilon$, $\Delta v_{\frac{1}{2}}$ and $A$ are the band frequency, the molar absorption coefficient, the band width at half-intensity and the integrated intensity of the $\mathrm{C}=\mathrm{O}$ stretching vibration ( $v_{\mathrm{C}=0}$ ) bands, respectively, and $N$ and $h(=100-N)$ are the percentage of non-hydrogen-bonded and hydrogen-bonded molecules, respectively. It was assumed that the $\varepsilon$ value of the free $v_{\mathrm{C}=0}$ band in $1-3$ is equal to that of lauric acid $\left[\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{10} \mathrm{CO}_{2} \mathrm{H}\right]$ because the $\mathrm{p} K_{\mathrm{a} 1}$ and $\mathrm{p} K_{\mathrm{a} 2}$ values of $\mathrm{HO}_{2} \mathrm{C}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{CO}_{2} \mathrm{H}$, for which $n>2$ are almost constant. ${ }^{9}$

In $\mathrm{CCl}_{4}$ solution, the $A$ value $\left(10^{-8} \mathrm{~cm}^{2} \mathrm{~s}^{-1}\right.$ molecule ${ }^{-1}$ ) of the

IVc $\tau_{1}=180^{\circ}, \tau_{2}=0^{\circ}$
free $v_{\mathrm{C}=0}$ band at $1758.7 \mathrm{~cm}^{-1}$ and the $A$ value per $\nu_{\mathrm{C}=0}$ band of dimer at $1710.5 \mathrm{~cm}^{-1}$ for lauric acid are 133 and 170 , respectively. ${ }^{2}$ Because compounds $1-3$ have two carboxy groups, their total $A$ values of the observed $v_{\mathrm{C}=0}$ bands were presumed to be between 266 and 340 . The total $A$ values of these compounds at $c a .3 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$ in $\mathrm{CCl}_{4}$ solution were in this region. However, when these solutions of 1 and 2 were diluted to a concentration (c) below $5 \times 10^{-6} \mathrm{~mol} \mathrm{dm}^{-3}$, the total $A$ values were reduced to a value below 200 , in spite of the fact that they show the hydrogen-bonded $v_{\mathrm{C}=0}$ bands. Therefore, we assumed that the total $A$ value of these compounds at $c<5 \times 10^{-6} \mathrm{~mol} \mathrm{dm}{ }^{-3}$ is 290 because the free molecules increase, and their $c$ values were estimated using this $A$ value. Although the estimated $c$ value changes slightly with each measurement, the variation of the $N$ value was within $\pm 2 \%$. The ab initio MO calculation ${ }^{8 a}$ was carried out on a VAX

${ }^{a} \mathrm{~F}$ and H show free and intermolecular hydrogen-bonded $\nu_{\mathrm{C}=0}$ bands, respectively. ${ }^{b}$ Percentage ( $N$ ) of non-hydrogen-bonded molecules, $N=$ $[\varepsilon /(2 \times 501.9)] \times 100$, where 501.9 is the true $\varepsilon$ value of free $v_{\mathrm{C}=0}$ band of lauric acid and its value was doubled because compounds $1-3$ have two carboxy groups. ${ }^{2}$ c Percentage $(h)$ of the double cyclic intermolecular hydrogen bonded molecules, where $h=100-N .{ }^{d}$ Concentration. ${ }^{e}$ Since compound 3 shows two free $v_{\mathrm{C}=\mathrm{o}}$ bands, it was assumed that the $\varepsilon$ value for this compound is equal to the sum of the $\varepsilon$ values for these bands. ${ }^{\delta}$ The band may be overlapped by the dimer $v_{\mathrm{C}=0}$ band of the Ib type. Assuming that the free molecules of $2 N \%$ in $1-3$ exist in equilibrium with dimers of the Ib type as well as in lauric acid, where the $N$ value was doubled because compounds $1-3$ have two carboxy groups, the percentages ( $\sigma$ ) of their dimers were estimated using the equations, ${ }^{4.6} c_{f}=2 N c / 100, \log c_{f}=0.245 \sigma_{0}^{\frac{1}{0}}-5.492$, and $\sigma=\sigma_{0} N / 100$, where $c_{f}$ is the concentration of free molecules, $c$ is the total concentration, and $\sigma_{0}$ is the percentage of the dimers at $c_{\mathrm{f}}$. The estimated $\sigma$ values showed the value of $2 \%$ for $1,0 \%$ for 2 and $10 \%$ for 3 , although the application of these equations may overestimate the $\sigma$ values because the assumption neglects the equilibrium between the free molecules and the dimers of the II type. Regression analysis was done between the $c$ and $\sigma$ values using the spectral parameters of lauric acid reported by us. ${ }^{2}$ The analysis gave the equation, $\log c=0.287 \sigma^{\frac{1}{2}}-5.484(n=7, r=0.99)$. If the intermolecular hydrogen bonds II in 1-3 are not formed, the $\sigma$ value is approximately estimated using the equation, $\log 2 c=0.287 \sigma^{\frac{1}{2}}-5.484$, where the $c$ value is doubled because these compounds have two carboxy groups.

## Results and Discussion

No Intramolecular Hydrogen Bonding in 1-3.-The spectral parameters of the $v_{\mathrm{C}=\mathrm{O}}$ bands in 1-3 and their assignments are listed in Table 1, together with the $N$ and the $h$ values. These FTIR spectra and the results of the peak separation of their spectra are shown in Fig. 1. For compounds 1 and 2, the intensities of the free $v_{\mathrm{C}=0}$ bands at 1759.5 and $1759.4 \mathrm{~cm}^{-1}$ for the carboxy groups decreased and new $v_{\mathrm{C}=\mathrm{O}}$ bands appeared at 1722.8 and $1708.4 \mathrm{~cm}^{-1}$ and at 1721.2 and $1705.7 \mathrm{~cm}^{-1}$, respectively. Also the intensities of the $v_{\mathrm{C}=\mathrm{o}}$ bands at 1760.1 and $1746.5 \mathrm{~cm}^{-1}$ in 3 decreased and new $v_{\mathrm{C}=0}$ bands appeared at 1722.1 and $1707.5 \mathrm{~cm}^{-1}$; the former bands were assigned to the free $v_{\mathrm{C}=0}$ bands because they agreed with the free $v_{\mathrm{C}=0}$ bands at 1760.1 and $1746.3 \mathrm{~cm}^{-1}$, which were observed for tertbutylacetic acid $\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CH}_{2} \mathrm{CO}_{2} \mathrm{H}\right] 4$ in $\mathrm{CCl}_{4}$ solution. Correspondingly, the intensities of the free OH stretching vibration (free $v_{\mathrm{OH}}$ ) bands at $3533.0 \mathrm{~cm}^{-1}$ in $1,3531.1 \mathrm{~cm}^{-1}$ in 2 and $3529.0 \mathrm{~cm}^{-1}$ in 3 decreased and the broad bands appeared at ca. $3000 \mathrm{~cm}^{-1}$, respectively. The free $v_{\mathrm{OH}}$ band of 3 also agrees with the free $v_{\mathrm{OH}}$ band at $3529.6 \mathrm{~cm}^{-1}$ in 4 . These results indicate that compounds 1-3 form the intermolecular hydrogen bonds Ib-IIb and/or the intramolecular hydrogen bonds IIIaIVc. In addition, the structural information from the free $v_{\mathrm{OH}}$ and the free $v_{\mathrm{C}=\mathrm{o}}$ bands can be expected because these bands are altered by the compounds.

If compounds $\mathbf{1 - 3}$ form the intramolecular hydrogen bonds between the carboxy groups, these compounds are presumed to exist in the conformations IIIa, IIIb, IVa, IVb or IVc. Usually the free $v_{\mathrm{C}=0}$ band of aliphatic carboxylic acids in $\mathrm{CCl}_{4}$ solution appears at $c a .1760 \mathrm{~cm}^{-1}$ and its carboxy group exists in the conformation Va. ${ }^{3}$ When R of Va was substituted by OMe and OPh groups an equilibrium existed between the conformers $\mathbf{V a}$ and $\mathbf{V b}$ and the free $v_{\mathrm{C}=0}$ band of the latter conformer shifted to higher wavenumber ( $\Delta v c a .30 \mathrm{~cm}^{-1}$ ) than that of the former. ${ }^{3}$ Furthermore, although the frequency of the free $v_{\mathrm{C}=\mathrm{O}}$ band of $\mathbf{V c}$ is not available, it is presumed to be higher
than that of $\mathbf{V b}$ or $\mathbf{V}^{\prime} \mathbf{b}$ because the $\mathbf{C = O}$ bond lengths calculated for formic acid by the ab initio MO method became shorter in the order of the conformers of the Va, $\mathbf{V}^{\prime} \mathbf{b}$ and Vctypes. ${ }^{10}$ For all compounds, the $v_{\mathrm{c}=0}$ band was not observed at wavenumber higher than $1760 \mathrm{~cm}^{-1}$. The results indicate that these compounds do not form the intramolecular hydrogen bonds IVb and IVc with the carboxy group which corresponds to the $\mathbf{V c}$ and the $\mathbf{V}^{\prime} \mathbf{b}$ types, respectively. In addition, the intramolecular hydrogen bond may not be formed between the OH and $\mathrm{C}=\mathrm{O}$ moieties in the carboxy group of the Va type because the conformational behaviour of the $\mathrm{C}=\mathrm{O}$ bond length calculated for methyl formate is similar to that of formic acid. ${ }^{10}$

In order to investigate the existence of the intramolecular hydrogen bonds IIIa, IIIb and IVa, these geometries of 1 were optimized using the $3-21 \mathrm{G}\left({ }^{*}\right)$ basis set. This was not done for IVb and IVc because they were not observed. The results obtained are given in Table 2 and the geometries of the linear conformer VIa and the U-shaped ones VIIa, VIIb and VIII are shown in Fig. 2. These calculations showed that the conformer VIIa which corresponds to the IIIa type is more stable than the linear one VIa and the conformer VIII which corresponds to the IVa type is slightly less stable. However, the $\mathrm{O} \cdots \mathrm{H}$ distances of these conformers are much larger than the sum ( $2.6 \AA$ ) of the van der Waals radii of these atoms. On the other hand, VIIb which corresponds to the IIIb type became extremely unstable, in spite of the fact that its $\mathrm{O} \cdots \mathrm{H}$ distance is shorter than $2.6 \AA$. These results suggest that compounds $1-3$ do not form the intramolecular hydrogen bonds IIIa, IIIb and IVa. Thus, these compounds $1-3$ do not form any intramolecular hydrogen bonds.
The carboxy groups of the conformers VIa, VI'a, VIIa and VIII exist in planar conformation as in Va. The conformer VIa is slightly more stable than the conformer VI'a, in which the carboxy groups lie in the same plane, while the conformer VIb, in which the $\tau$ values were changed from 0 to $90^{\circ}$, becomes extremely unstable. These results also suggest that intramolecular hydrogen bonds of the type IIIb and the IVb are not formed.

Double Cyclic Intermolecular Hydrogen Bonding in 1-3.-Fig. 3 shows plots of $c$ against the $h$ values for 1-3. These $h$ values

Fig. 1 FTIR spectra of 1-3 in $\mathrm{CCl}_{4}$ solution and the results of peak separation of their spectra. Spectra were obtained using a 5.0 cm cell; (a): $1,2.8459 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3},(b): 2,2.9696 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$ and (c): 3, $2.7099 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$.

Vb $\tau=180^{\circ}$

Vb $\tau=180^{\circ}$

Vc $\tau=90^{\circ}$
decrease with decreasing $c$ value, which demonstrates that compounds 1-3 form the intermolecular hydrogen bonds Ib and/or II. If the intermolecular hydrogen bonds II in 1-3 are not formed, the percentage of dimers Ib of the Ia type are estimated to be $19 \%$ at $3 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$ (see Table 1, footnote $f$ ). Fig. 3 shows a high $h$ value of $73 \%$ for $1,85 \%$ for 2 and $44 \%$ for 3 at $3 \times 10^{-5} \mathrm{~mol} \mathrm{dm}{ }^{-3}$. This suggests that these compounds form the intermolecular hydrogen bonds IIa and/or IIb.

Since the carboxy groups in the conformers VIIa and VIII of 1 are approximately parallel to each other, although these

groups do not completely overlap, it is possible to form the intermolecular hydrogen bonds IIa and IIb. However, it was surmised that the intermolecular hydrogen-bonded structure of 1 is the IIa type so that the conformer VIIa is the most stable. As shown in Fig. 2, the conformation VIIa has exo and endo hydrogen atoms at the 3 -position. Therefore, it was presumed that, in 2, the stability of the conformer of the VIIa type increases because the compound can assume the exo-methyl conformation, but in 3 , its stability decreases due to the steric interaction between the endo-3-methyl and the carboxy groups. This agreed with the observed order of the $h$ values i.e. $3<1<2$. As the FTIR spectra of compound 2 could be measured over the large range of $3 \times 10^{-4}-1.9 \times 10^{-6} \mathrm{~mol}$ $\mathrm{dm}^{-3}$, its association constant ( $K$ ) was estimated from the concentration dependence of the $v_{\mathrm{C}=0}$ band at $c a .1721 \mathrm{~cm}^{-1}$ as previously described. ${ }^{2}$ The obtained $K$ value of $7.7 \times 10^{4} \mathrm{dm}^{3}$ $\mathrm{mol}^{-1}$ (data points $=6$, correlation coefficient $=0.997$ ) is much larger than the $K$ value of lauric acid, $3.1 \times 10^{3} \mathrm{dm}^{3} \mathrm{~mol}^{-1}{ }^{2}$ As shown in Fig. 3, the tendency of the characteristic curves for 1-3 differs from that of lauric acid. From these results, it is clear that compounds $1-3$ in $\mathrm{CCl}_{4}$ solution form the double cyclic intermolecular hydrogen bonds IIa.

IXa

IXb

In addition, compounds $1-3$ exhibit two intermolecular hydrogen-bonded $v_{\mathrm{C}=0}$ bands. The ratios of the intensities of these bands are nearly constant at the concentrations examined. These findings suggest that these compounds contain two conformers of a chair IXa and a boat form IXb with a 16membered ring formed by intermolecular hydrogen bonds IIa.

In conclusion, we found that compounds $1-3$ form double cyclic intermolecular hydrogen bonds involving a 16-membered
ring, but not intramolecular hydrogen bonds. This information should be helpful for understanding the hydrogen bonds of dicarboxylic acids and studying molecular recognition and the interaction between drug and receptor.
