# Kinetics and Mechanism of the Aminolysis of Phenyl Dithioacetate in Aqueous Solution 

Enrique A. Castro,* Fernando Ibáñez, José G. Santos and Carmen Ureta<br>Facultad de Quimica, Pontificia Universidad Católica de Chile, Casilla 306, Santiago 22, Chile

#### Abstract

The reactions of the title substrate with a series of secondary alicyclic amines have been subjected to a kinetic study in water at $25^{\circ} \mathrm{C}$, ionic strength $0.2 \mathrm{~mol} \mathrm{dm}{ }^{-3}$. Under amine excess pseudo-first-order rate coefficients ( $k_{\text {obs }}$ ) are found throughout. The order in amine varies from 1-2 according to the amine basicity and the experimental conditions. A general reaction scheme with a zwitterionic and an anionic tetrahedral intermediate (1 and 2, respectively) accounts for the rate equations found. The $\mathrm{p} K_{\mathrm{a}}$ of 1 is estimated along with some microconstants in the scheme. From the values of the microconstants, either obtained experimentally or estimated, it is deduced that 1 is more stable than its analogue (3) formed in the aminolysis of $S$-phenyl thioacetate, and therefore, 1 has time for proton transfer to a base to yield 2. The rate coefficients for expulsion of an amine ( $k_{-1}$ ) and $\mathrm{PhS}^{-}$ $\left(k_{2}\right)$ from 1 are both smaller than those for expulsion from 3. The Brønsted plots for $k_{1}$ (rate coefficient for formation of 1$), K_{1}\left(=k_{1} / k_{-1}\right)$ and $k_{-1}$ have slopes $\beta=0.2,1.2$ and -1.0 , respectively. The $\mathrm{p} K_{\mathrm{a}}$ value of an (hypothetical)amine for which $k_{-1}=k_{2}$ is deduced: $\mathrm{p} K_{\mathrm{a}}{ }^{\circ}=10.3 \pm 0.5$, which is smaller than that derived from the aminolysis of $S$-phenyl thioacetate ( $\mathrm{p} K_{\mathrm{a}}{ }^{\circ}=12.2$ ).

Although the mechanism of the hydrolysis and aminolysis of oxyesters and oxycarbonates is well established, ${ }^{1.2}$ that of the corresponding reactions of thiolesters and thiocarbonates is not well understood, despite some studies carried out in water as well as in aprotic solvents. ${ }^{3.4}$

We have recently studied the aminolysis of $S$-aryl thioacetates in aqueous solution and deduced, through non linear structurereactivity relationships, the existence of a zwitterionic tetrahedral intermediate ( $\mathrm{T}^{ \pm}$) in the reaction path. ${ }^{5.6}$ The mechanism of these reactions is described by eqn. (1), where -NH represents a secondary alicyclic amine. It was found that the $k_{2}$ step was faster than the rate of proton transfer from $\mathbf{T}^{ \pm}$ to a base to yield an anionic intermediate $T^{-} .5 .6$

In one of the works above we also analysed the influence of the nature of the amine on the reaction mechanism. ${ }^{6}$ The effect of the non-leaving group of the substrate on the mechanism has also been studied in the aminolysis of oxyesters and oxycarbonates. ${ }^{2.7}$

In this work we examine the influence of the thiocarbonyl group of the substrate on the mechanism of the above reactions, by comparing the results of the present work with those found in the aminolysis of $S$-phenyl thioacetate. ${ }^{5}$ We find in the present work that there is a remarkable difference in the mechanism of these two reactions caused by the much higher stability of $\mathrm{T}^{ \pm}$ formed in the present reactions. As a result of this the lifetime of the latter is long enough to allow proton transfer to a base to yield $\mathrm{T}^{-}$. This rate of proton transfer is comparable or faster than the rate of $\mathrm{PhS}^{-}$expulsion from this $\mathrm{T}^{ \pm}$species.
sodium phosphate dibasic from Fluka, both analytical reagent grade, were used without further purification to prepare some of the buffered solutions. Potassium chloride from Merck, analytical grade, was used to maintain the ionic strength of the solutions.

Phenyl dithioacetate (PDTA) was prepared from 2,4-bis-(phenylthio)-1,3-dithia-2,4-diphosphetane 2,4-disulfide (PDD) and acetic acid, according to a reported procedure. ${ }^{8}$ PDTA was identified by its ${ }^{1} \mathrm{H}$ NMR and IR spectra. PDD was synthesized as described previously. ${ }^{8}$

Kinetic Measurements.-The reactions were studied spectrophotometrically, following the appearance of benzenethiol and/or its conjugate base at 264 nm , by means of a PerkinElmer Lambda 3 spectrophotometer. After thermal equilibration of the kinetic samples in 1 cm cells placed in the thermostatted compartment of the instrument $\left(25.0 \pm 0.1^{\circ} \mathrm{C}\right)$, the reactions were started by addition ( $5-15 \mathrm{~mm}^{3}$ ) of a stock solution of PDTA in acetonitrile. The initial PDTA concentration was ( $1-3$ ) $\times 10^{-5} \mathrm{~mol} \mathrm{dm}{ }^{-3}$ and acetonitrile never exceeded $0.5 \%$ in the kinetic solutions.
Borate and phosphate buffers were used in some cases to maintain the pH . In other cases the amine and its conjugate acid acted as such. At least three pH values were employed in the reactions of each amine. The reaction conditions are described in Table 1.

Pseudo-first-order rate coefficients ( $k_{\text {obs }}$ ) were obtained under amine excess (at least twenty-fold, although usually the excess was well over this). The values of $k_{\text {obs }}$ found are shown in Table 1.

Product Studies.-The UV spectrum obtained at the end of the reaction of the substrate with piperidine, $[\text { PDTA }]_{0}=2 \times$ $10^{-5} \mathrm{~mol} \mathrm{dm}^{-3},[\mathrm{~N}]_{\text {tot }}=0.01 \mathrm{~mol} \mathrm{dm}^{-3}$, borate buffer 0.01 mol $\mathrm{dm}^{-3}$ and $\mathrm{pH}=8.7$, was identical to the one found for benzenethiolate anion under the same conditions ( $\lambda_{\text {max }}=264 \mathrm{~nm}$ ).

## Results and Discussion

The rate law obtained in all the present reactions is given by eqn. (2), the amine being in excess over the substrate (PDTA) in all

[ N$]$ in 0.1 $\mathrm{mol} \mathrm{dm}{ }^{-3}$ phosphate buffer and from the limiting value of $k_{\text {obs }}$ at high [B]; the individual $k_{1}$ values are 76,64 and $61 \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$, respectively.
absence of external buffer a pH-independent linear plot of $k_{\text {obs }}$ vs. $[\mathrm{N}]^{2}$ was obtained (not shown).

According to the kinetic behaviour exhibited by the present reactions (Figs. 1-4 and the linear plots), a general expression for $k_{\text {obs }}$ can be deduced, eqn. (3), which is consistent with the

$$
\begin{equation*}
k_{\mathrm{obs}}=\frac{k_{1}\left(k_{2}+k_{3}^{\mathrm{N}}[\mathrm{~N}]+k_{3}^{\mathrm{B}}[\mathrm{~B}]+k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]\right)[\mathrm{N}]}{k_{-1}+k_{2}+k_{3}^{\mathrm{N}}[\mathrm{~N}]+k_{3}^{\mathrm{B}}[\mathrm{~B}]+k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]} \tag{3}
\end{equation*}
$$

general mechanism shown in Scheme 1. Applying the steady state condition to intermediates 1 and 2 of the scheme and assuming $\quad k_{4} \gg k_{-3}=k_{-3}^{\mathrm{NH}}\left[\mathrm{NH}^{+}\right]+k_{-3}^{\mathrm{BH}}[\mathrm{BH}]+k_{-3}^{\mathrm{W}}\left[\mathrm{H}_{2} \mathrm{O}\right]$, one obtains eqn. (3) $\left(\mathrm{NH}^{+}\right.$and BH are the conjugate acids of N and $B$; the latter represent the free bases of the amine and the external buffer, respectively).

Eqn. (3) can be simplified according to the conditions of the reactions (Table 1) and the nature of the amine.

In the reactions with PI , in the presence of borate buffer, $k_{2}+$ $k_{3} \gg k_{-1}$, where $k_{3}=k_{3}^{\mathrm{N}}[\mathrm{N}]+k_{3}^{\mathrm{B}}[\mathrm{B}]+k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]$, and eqn.
(3) reduces to eqn. (4). This inequality will be justified later,

$$
\begin{equation*}
k_{\mathrm{obs}}=k_{1}[\mathrm{~N}] \tag{4}
\end{equation*}
$$

together with the ones below for the reactions of the other amines. The value of $k_{1}$ was obtained as the slope of a plot of $k_{\text {obs }}$ vs. [ N ]. The value is shown in Table 2.

In the reactions of the substrate with PA , in the presence of borate buffer, $k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]$is negligible at the pH values used (Table 1), compared to the other terms in eqn. (3). Therefore, in this case eqn. (3) simplifies to eqn. (5), which accounts for the

$$
\begin{equation*}
k_{\mathrm{obs}}=\frac{k_{1}\left(k_{2}+k_{3}^{\mathrm{N}}[\mathrm{~N}]+k_{3}^{\mathrm{B}}[\mathrm{~B}]\right)[\mathrm{N}]}{k_{-1}+k_{2}+k_{3}^{\mathrm{N}}[\mathrm{~N}]+k_{3}^{\mathrm{B}}[\mathrm{~B}]} \tag{5}
\end{equation*}
$$

plots shown in Fig. 1. The pH dependence of the curves can be attributed to the variation of [B] with the pH values.

In the reactions with PA at variable [B] (borate) and constant $[\mathrm{N}]$ and pH , according to the reaction conditions $k_{3}^{\mathrm{B}}[\mathrm{B}] \gg k_{2}+k_{3}^{\mathrm{N}}[\mathrm{N}]+k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]$; therefore eqn. (3) yields eqn. (6), which accounts for the plot found (similar to that in Fig. 3). Rearrangement of eqn. (6) gives eqn. (7), where $K_{1}=$

$$
\begin{equation*}
k_{\mathrm{obs}}=\frac{k_{1} K_{3}^{\mathrm{B}}[\mathrm{~B}][\mathrm{N}]}{k_{-1}+k_{3}^{\mathrm{B}}[\mathrm{~B}]} \tag{6}
\end{equation*}
$$

$k_{1} / k_{-1}$ is the equilibrium constant for the first step of Scheme 1. Eqn. (7) describes the linear plot obtained (not shown); the

$$
\begin{equation*}
\frac{[\mathrm{B}]}{k_{\mathrm{obs}}}=\left(K_{1} k_{3}^{\mathrm{B}}[\mathrm{~N}]\right)^{-1}+\left(k_{1}[\mathrm{~N}]\right)^{-1}[\mathrm{~B}] \tag{7}
\end{equation*}
$$

values of $K_{1} k_{3}^{\mathbf{B}}$ and $k_{1}$ were obtained from the intercept and slope, respectively, of this plot. From an estimation of the value of $k_{3}^{\mathbf{B}} \approx 3 \times 10^{9} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ (see below), the value of $K_{1}$ can be found; the value of $k_{-1}$ can also be determined knowing $K_{1}$ and $k_{1}$. These values are shown in Table 2.

In the reactions with BHPA in the absence of buffer the term $k_{3}^{\mathrm{B}}[\mathrm{B}]=0$, so eqn. (3) reduces to eqn. (8), under the reaction

$$
\begin{equation*}
k_{\mathrm{obs}}=\frac{k_{1}\left(k_{2}+k_{3}^{\mathrm{N}}[\mathrm{~N}]+k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]\right)[\mathrm{N}]}{k_{-1}+k_{2}+k_{3}^{\mathrm{N}}[\mathrm{~N}]+k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]} \tag{8}
\end{equation*}
$$

conditions (Table 1), which accounts for the plots in Fig. 2.
In the presence of $0.2 \mathrm{~mol} \mathrm{dm}^{-3}$ borate buffer, however, the above reaction exhibits a linear plot of $k_{\text {obs }} v s$. [ N ] which obeys eqn. (4), i.e., in this case $k_{-1}$ is negligible compared to the sum of the other terms in the denominator of eqn. (3), and this equation reduces to eqn. (4). The value of $k_{1}$, obtained as the slope of the above plot, is shown in Table 2.

For the reaction of PDTA with BHPA at constant [N] and pH in the presence of varying [B], $k_{3}^{\mathrm{B}}[\mathrm{B}] \approx k_{-1} \gg k_{2}+k_{3}^{\mathrm{N}}[\mathrm{N}]+$ $k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]$; hence eqn. (3) simplifies to eqn. (6), which accounts for the plot in Fig. 3. From the linear plot of [B] $/ k_{\text {obs }} v s$. [B] (not shown), $K_{1} k_{3}^{\mathrm{B}}$ and $k_{1}$ were obtained from the intercept and slope, respectively [see eqn. (7)]. The value of $k_{1}$ agrees with that previously determined from eqn. (4) (Table 2). From an estimation of $k_{\mathrm{B}} \approx 5 \times 10^{9} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ (see below), the values of $K_{1}$ and $k_{-1}$ were obtained; these are shown in Table 2.

The reaction of PDTA with MO without external buffer obeys eqn. (9), under the reaction conditions (Table 1), i.e., $k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]$

$$
\begin{equation*}
k_{\mathrm{obs}}=\frac{k_{1}\left(k_{2}+k_{3}^{\mathrm{N}}[\mathrm{~N}]\right)[\mathrm{N}]}{k_{-1}+k_{2}+k_{3}^{\mathrm{N}}[\mathrm{~N}]} \tag{9}
\end{equation*}
$$

is negligible compared with the other terms in eqn. (3). Eqn. (9) accounts for the plot of Fig. 4. If the [N] range is restricted to $(2.3-60) \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$, instead of $(1.0-60) \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$

Fig. 5 Bronsted plot for $k_{1}$ ( $p K_{\mathrm{a}}$ statistically corrected) obtained in the reactions of PDTA with PA, BHPA, MO, FPA and PAH

Fig. 6 Brønsted plot for $K_{1}$ (statistically corrected) obtained in the reactions of PDTA with PI, PA, BHPA, MO, FPA and PAH

Fig. 7 Brønsted plot for $k_{1}$ (statistically corrected obtained in the reactions of PDTA with PI, PA, BHPA, MO and FPA
in Fig. $4, k_{3}^{\mathrm{N}}[\mathrm{N}]>k_{2}$ and eqn. (9) reduces to eqn. (10), which

$$
\begin{equation*}
k_{\mathrm{obs}}=\frac{k_{1} k_{3}^{\mathrm{N}}[\mathrm{~N}]^{2}}{k_{-1}+k_{3}^{\mathrm{N}}[\mathrm{~N}]} \tag{10}
\end{equation*}
$$

rearranges to eqn. (11). This expression accounts for the linear

$$
\begin{equation*}
\frac{[\mathrm{N}]}{k_{\mathrm{obs}}}=k_{1}^{-1}+\left(K_{1} k_{3}^{\mathrm{N}}\right)^{-1}[\mathrm{~N}]^{-1} \tag{11}
\end{equation*}
$$

plot of $[\mathrm{N}] / k_{\text {obs }} v s$. $1 /[\mathrm{N}]$ found (not shown); the values of $k_{1}$ and $K_{1} k_{3}^{\mathrm{N}}$ were obtained from the intercept and slope, respectively, of this plot. From the estimation of $k_{3}^{\mathrm{N}}=10^{10} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ (see below) the values of $K_{1}$ and $k_{-1}$ can be determined (Table 2).

For the above reaction in $0.1 \mathrm{~mol} \mathrm{dm}^{-3}$ phosphate buffer, $k_{-1}$ is negligible compared to the sum of the other terms in the denominator of eqn. (3), so this expression simplifies to eqn. (4), which accounts for the linear and pH independent plot of $k_{\text {obs }} v s$. [ N$]$ (not shown). The value of $k_{1}$ obtained as slope of this plot (Table 2) agrees with the value determined from the plot of eqn. (11).

Another determination of $k_{1}$ is possible from a plot of $k_{\mathrm{obs}} v s$. [B] (phosphate) at constant [ N$]$ and pH (not shown; conditions in Table 1). The plot levels off (similarly to that in Fig. 3) and $k_{1}$ is the limiting value of $k_{\text {obs }} /[\mathrm{N}]$, i.e., in eqn. (6) $k_{3}^{\mathrm{B}}[\mathrm{B}] \gg k_{-1}$ at high [B]. This value of $k_{1}$ (shown in Table 2) agrees with the values determined above.

In the reaction of PDTA with FPA without external buffer, under the reaction conditions, $k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]$is negligible and eqn. (9) holds. This equation accounts for the $k_{\text {obs }} v s$. [N] plot obtained (not shown, but similar to that of Fig. 4). Using a more restricted [ N ] range, ( $3-20$ ) $\times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$ instead of ( $1-20$ ) $\times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$, the plot $[\mathrm{N}] / k_{\text {obs }} v s .1 /[\mathrm{N}]$ is linear (not shown), i.e., under the new conditions $k_{3}^{N}[\mathrm{~N}]>k_{2}$ and eqn. (9) reduces to eqns. (10) and (11). From a plot of the latter equation the values of $k_{1}$ and $K_{1} k_{3}^{\mathrm{N}}$ were obtained; since $k_{3}^{\mathrm{N}}=10^{10} \mathrm{~s}^{-1}$ $\mathrm{mol}^{-1} \mathrm{dm}^{3}$ (see below) the values of $K_{1}$ and $k_{-1}$ can also be determined; all these values are shown in Table 2.
The above reaction in the presence of borate buffer shows linear plots of $k_{\text {obs }} v s$. [ N ], where the slopes increase with pH (plots not shown). In this case $k_{3}^{\mathrm{B}}[\mathrm{B}] \gg k_{3}^{\mathrm{N}}[\mathrm{N}]+k_{2}, k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]$ is negligible and, therefore, eqn. (3) simplifies to eqn. (6). The latter accounts for the above linear plots; moreover, since [B] increases with pH ( $[\mathrm{B}]_{\text {tot }}$ is constant at the 3 pH values) the slopes should also do so.

In the reaction of the substrate with $\mathrm{PAH}, k_{-1} \gg k_{3}^{\mathrm{N}}[\mathrm{N}] \geqslant k_{2}$, $k_{3}^{\mathrm{OH}}\left[\mathrm{OH}^{-}\right]$is negligible and $k_{3}^{\mathrm{B}}[\mathrm{B}]=0$ (no external buffer was used), therefore eqn. (3) simplifies to eqn. (12). The linear and

$$
\begin{equation*}
k_{\mathrm{obs}}=\frac{k_{1} k_{3}^{\mathrm{N}}[\mathrm{~N}]^{2}}{k_{-1}} \tag{12}
\end{equation*}
$$

pH -independent plot of $k_{\text {obs }} v s$. $[\mathrm{N}]^{2}$ found (not shown) obeys eqn. (12); the value of $K_{1} k_{3}^{\mathrm{N}}$ was obtained as the slope of the plot. With the value of $k_{3}^{\mathrm{N}}=10^{10} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}, K_{1}$ can be determined. The value of $k_{1}$ for this reaction was obtained by extrapolation of the Br nnsted plot for $k_{1}$ in the reactions with the other amines, and the $k_{-1}$ value was determined from $K_{1}$ and $k_{1}$. The values are shown in Table 2.

In order to justify the above inequalities we will estimate some of the microconstants involved in Scheme 1. To do so we will first estimate the $\mathrm{p} K_{\mathrm{a}}$ of intermediate 1 in the scheme.

The $\mathrm{p} K_{\mathrm{a}}$ of the tetrahedral intermediate 3 has been estimated, based on Jencks's method, ${ }^{9}$ to be equal to that of the parent aminium ion. ${ }^{5}$ On the other hand, an increasing acidity of NH in the series $\mathrm{RNHCO}_{2} \mathrm{Ar}<\mathrm{RNHCOSAr}^{2}<\mathrm{RNHCS}_{2} \mathrm{Ar}$ has been found. ${ }^{10}$ There is also a $\mathrm{p} K_{\mathrm{a}}$ lowering of 3.5 units when

3
going from $N$-protonated $N$-alk ylcarbamates $\left(\mathrm{RNH}_{2}{ }^{+}-\mathrm{COO}^{-}\right)$ to the corresponding thiocarbamates and there is a further decrease in $\mathrm{p} K_{\mathrm{a}}$ from the latter compounds to dithiocarbamates. ${ }^{11}$ The $\mathrm{p} K_{\mathrm{a}}$ lowering in going from 3 to $\mathbf{1}$ cannot be as large as 3.5 units, ${ }^{4 h}$ and according to our results we estimate this $\mathrm{p} K_{\mathrm{a}}$ decrease to be ca. 0.3 units (see below). Therefore, the $\mathrm{p} K_{\mathrm{a}}$ of 1 is ca. $0.3 \mathrm{p} K_{\mathrm{a}}$ units lower than that of the parent aminium ion.
Since proton transfer from 1 to the corresponding amine is thermodynamically favourable, it follows that $k_{3}^{N}$ is $c a .10^{10} \mathrm{dm}^{3}$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1} .^{12}$ This proton transfer to $\mathrm{OH}^{-}$is also favourable ( $\mathrm{p} K_{\mathrm{a}}$ of $\mathrm{H}_{2} \mathrm{O}$ 15.7), therefore, $k_{3}^{\mathrm{OH}}$ is $c a .5 \times 10^{10} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ (larger than $k_{3}^{N}$ in view of the large diffusion coefficient of $\mathrm{OH}^{-}$ compared with that of the amine). ${ }^{12}$
The $\mathrm{p} K_{\mathrm{a}}$ of the intermediate 1 formed with PI is $11.2-0.3=$ 10.9. The proton transfer to $\mathbf{B}$ (borate base, $\mathrm{p} K_{\mathrm{a}}$ of $\mathbf{B H}=9.2$ ) is not thermodynamically favourable, therefore $k_{-3}^{\text {BH }} \approx 10^{10} \mathrm{dm}^{3}$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1}$ and $k_{3}^{\mathrm{B}} \approx 10^{10} \times 10^{-10.9} / 10^{-9.2} \approx 2 \times 10^{8} \mathrm{dm}^{3}$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1} .{ }^{12}$ In the reactions with PA a similar calculation yields $k_{3}^{\mathrm{B}}$ ca. $3 \times 10^{9} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$. The intermediate 1 formed with BHPA has a $\mathrm{p} K_{\mathrm{a}}$ similar to that of BH, therefore $k_{3}^{\mathrm{B}}$ is $c a$. $5 \times 10^{9} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1} .{ }^{12}$ For FPA, $k_{3}^{\mathrm{B}}$ is $c a .10^{10} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$, since the proton transfer from 1 to B (borate) is thermodynamically favourable. In the reactions with MO phosphate buffer was employed ( $\mathrm{p} K_{\mathrm{a}}=6.7$ ) and the $\mathrm{p} K_{\mathrm{a}}$ of $1(\mathrm{MO})$ is $c a$. 8.5 ; therefore $k_{3}^{\mathrm{B}}$ is ca. $1 \times 10^{8} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ in this case.

The results obtained in this work (Figs. 1-4 and other plots) are compatible with a value of $k_{2}$ within the range $10^{6}-10^{7} \mathrm{~s}^{-1}$. This value should be practically independent of the amine basicity, ${ }^{2.5 .6}$ so it is the same for all the zwitterionic intermediates formed in the present reactions. The uncertainty in $k_{2}$ is a consequence of its relatively small value compared to the sum of the other terms in the rate equations concerned [e.g. eqns. (5), (8) and (9)].
The values of the microconstants involved in Scheme 1 (either estimated or obtained experimentally, Table 2), although subject to rather large errors (see Table 2), justify the inequalities stated above regarding eqns. (4)-(12) and can describe satisfactorily the experimental plots found.
Another indication that the values of the microconstants of Table 2 are correct is given by the good correlations exhibited by the Brønsted plots for $k_{-1}$ and $K_{1}$ (Figs. 5 and 6). The corresponding plot for $k_{1}$ shows a satisfactory correlation (Fig. 7).
The absolute value of the Brønsted slope for $k_{-1}\left(\beta_{-1} c a .-1\right.$, Fig. 5) is larger than those exhibited in the aminolyses of aryl acetates $\left(\beta_{-1}=-0.7\right),{ }^{13}$ phenyl aryl carbonates ( $\beta_{-1}=$ $-0.7)^{2}$ and aryl thioacetates $\left(\beta_{-1}=-0.65\right){ }^{6}$ The Brønsted slope for $K_{1}\left(\beta_{\mathrm{eq}}=+1.2\right.$, Fig. 6) is comparable to that found in the aminolysis of phenyl aryl carbonates ( $\beta_{\mathrm{eq}}=+1.0$ ), ${ }^{2}$ and larger than those obtained in the aminolysis of aryl acetates and thiolacetates $\left(\beta_{\mathrm{eq}}=+0.85-0.9\right)^{1.6 .13}$ and 2,4-dinitrophenyl methyl carbonate and $p$-nitrophenyl benzoate ( $\beta_{\text {eq }}=+0.85-$ 0.9 ). ${ }^{4 a, 7 a . c}$ The Brønsted slope for $k_{1}\left(\beta_{1} c a .+0.2\right.$, Fig. 7) is the same as that found in the aminolysis of aryl acetates and thiolacetates and methyl aryl carbonates, ${ }^{1.6 .7}$ and a little smaller than that exhibited in the aminolysis of phenyl aryl carbonates ( $\beta_{1}=0.3$ ). ${ }^{2}$
With the $\beta$ values for $k_{-1}$ and $K_{1}$ found in the present reactions the $\beta$ value for $k_{1}$ can be deduced: $\beta_{1}=\beta_{\text {eq }}+\beta_{-1}=$ $1.2-1.0=0.2,{ }^{1.2}$ which coincides with the one obtained experimentally (Fig. 7).
With the values of $\beta_{1}$ and $\beta_{\mathrm{eq}}$ the effective charges can be assigned on the nitrogen atoms of the transition state for the first step (4) and of intermediate 1 , respectively. ${ }^{1.2}$ Since the sensitivity of the rate coefficient $k_{2}$ of Scheme 1 to the amine basicity is approximately zero in the aminolysis of aryl acetates and thiolacetates, ${ }^{1.26 .613}$ we will assume that it is also zero in the present reactions. This is reasonable in view of the impossibility
of the amine moiety in intermediate 1 exerting the push to expel $\mathrm{PhS}^{-} .^{1.2 .6 .13}$ Therefore, we can assume that the effective charge on the nitrogen atom of the transition state for the second step in Scheme 1 (5) is also +1.2 .

The greater effective charge on the nitrogen atom of intermediate $\mathbf{1}(+1.2)$ compared to that of $\mathbf{3}(+0.7)$ means that the group $\mathrm{MeC}\left(\mathrm{S}^{-}\right) \mathrm{SPh}$ is more electron-withdrawing than $\mathrm{MeC}\left(\mathrm{O}^{-}\right) \mathrm{SPh}$, and explains why the species 1 is more acidic than 3.

The reason for observing base catalysis in the present reactions, as opposed to the aminolysis of aryl thiolacetates which shows no base catalysis, ${ }^{5.6}$ is two fold: (i) In the present reactions proton transfer from $\mathbf{1}$ to a base to yield $\mathbf{2}$ is faster than in the aryl thiolacetates reactions due to the higher acidity of 1 . (ii) The rate of expulsion of both $\mathrm{PhS}^{-}$and a given amine is slower from intermediate $\mathbf{1}$ than from $3,{ }^{5.6}$ therefore $\mathbf{1}$ is more stable than 3 and proton transfer from 1 can successfully compete with $k_{2}$.

The higher stability of intermediate $\mathbf{1}$ relative to $\mathbf{3}$ is in agreement with the fact that $S, S$-acetals decompose in water more slowly than $O, S$-acetals and $O, O$-analogues. ${ }^{14}$ There are also many examples of tetrahedral intermediates whose stability increases as the number of sulfur atoms attached to the central carbon increases. ${ }^{15}$

According to our results the ability of $\mathrm{S}^{-}$in intermediate 1 to form a double bond with the tetrahedral carbon and expel a leaving group is less than that of $\mathrm{O}^{-}$in 3 . This is in accord with the known $\mathrm{C}^{+}-\mathrm{S}^{-}$character of the thione 'double' bond resulting from a weaker $\pi$-bonding energy compared with that of the carbonyl group. ${ }^{10 b}$ There is a $170 \mathrm{~kJ} \mathrm{~mol}^{-1}$ difference between the $\pi$-bond energy of $\mathrm{C}=\mathrm{S}$ and $\mathrm{C}=\mathrm{O} .{ }^{16}$ As a result of this, $k_{1}$ is larger in the present reactions compared to the same reactions with $S$-phenyl thioacetate (PTA). ${ }^{5.6 . *}$ Once the intermediate 1 is formed the difficulty in reforming the CS double bond and expelling either the amine or $\mathrm{PhS}^{-}$is greater compared with the formation of the CO double bond in $3 .{ }^{17}$ It is difficult to find analogies in the literature, but the slower expulsion of $\mathrm{PhO}^{-}$from $\mathrm{ArN}^{-} \mathrm{CSOPh}$ in comparison with the same expulsion from $\mathrm{ArN}^{-} \mathrm{COOPh}$ and the slower leaving rate of $\mathrm{PhS}^{-}$from $\mathrm{ArN}^{-} \mathrm{CSSPh}$ relative to $\mathrm{ArN}^{-} \mathrm{COSPh},{ }^{10 a}$ are somehow in agreement with our results in view of the contribution of the canonical structure $\mathrm{ArN}=\mathrm{C}\left(\mathrm{X}^{-}\right)(\mathrm{XPh})$, ( $\mathrm{X}=\mathrm{O}$ or S ), to the ground state of the X -phenyl $N$-aryl(thio)carbamate. ${ }^{10 b}$

The $\mathrm{p} K_{\mathrm{a}}$ value for the centre of the hypothetical Brønsted plot for $k_{\mathrm{N}}\left(\mathrm{p} K_{\mathrm{a}}{ }^{0}\right)$, i.e., the value of the basicity of an amine for which $k_{-1}=k_{2}{ }^{6}$ can be obtained for the present reactions by equalising the Bransted equation for $k_{-1} \dagger$ with the value of $k_{2}$ (Table 2). ${ }^{6}$ For the lower and upper limits of $k_{2}$, the resulting values of $\mathrm{p} K_{\mathrm{a}}{ }^{0}$ are 10.8 and 9.8 , respectively. The $\mathrm{p} K_{\mathrm{a}}{ }^{0}$ value deduced for the reactions of PTA with secondary alicyclic amines is $12.2 .{ }^{6}$ The higher value of $\mathrm{p} K_{\mathrm{a}}{ }^{0}$ for the PTA reactions

[^0]is consistent with the fact that a linear Brønsted plot was found in the aminolysis of $p$-nitrophenyl benzoate ( $\mathrm{p} K_{\mathrm{a}}{ }^{0}>11$ ), whereas a curved one with $\mathrm{p} K_{\mathrm{a}}{ }^{0}=9.2$ is exhibited in the same reactions with $O-p$-nitrophenyl thiobenzoate. ${ }^{4 a}$

Campbell and Lapinskas ${ }^{4 a}$ have interpreted their results in terms of a lower stability of the tetrahedral intermediate formed in the reactions of the thioester compared to that formed in the aminolysis of the oxyesters; they claim that $\mathrm{S}^{-}$in the former intermediate is able to expel $p$-nitrophenoxide ion with greater driving force than can $\mathrm{O}^{-}$from the oxy intermediate.

Our results disagree with the above interpretation and indicate that the change of $\mathrm{O}^{-}$in the intermediate to $\mathrm{S}^{-}$ increases the stability of the intermediate by decreasing the nucleofugalities of both the amine and $\mathrm{PhS}^{-}$from this compound.

The ratio $k_{-1} / k_{2}$ for an amine isobasic with $\mathrm{PhS}^{-} \quad\left(\mathrm{p} K_{\mathrm{a}}\right.$ $\mathrm{PhSH}=6.5)^{5}$ from intermediate 3 is $c a .5 \times 10^{3}{ }^{5.6}$ whereas the same ratio from 1 is $c a .10^{3}-10^{4}$, depending on the limiting $k_{2}$ values used (Table 2). In both cases, the conclusion is that amines are much better leaving groups than isobasic arylthiolate ions. It has also been found that amines are much better nucleofuges from a zwitterionic intermediate ( $\mathrm{T}^{ \pm}$) than aryloxide ions of equal basicity. ${ }^{1.24 .4 .7 .13}$

We disagree with the claim that the change of $\mathrm{O}^{-}$to $\mathrm{S}^{-}$in $\mathrm{T}^{ \pm}$ favours aryloxide ion (or arylthiolate ion) expulsion, ${ }^{4 a}$ since the $k_{-1} / k_{2}$ ratio will vary differently with amine basicity due to the different sensitivities of $k_{-1}$ to this basicity ( $\beta_{-1}=0.65$ and 0.97 for the aminolysis of PTA and in this work, respectively). For instance, for an amine of $\mathrm{p} K_{\mathrm{a}} 12$ the $k_{-1} / k_{2}$ ratio is 1.4 and $0.01^{*}$ for the aminolysis of PTA and PDTA, respectively; nevertheless, for an amine of $\mathrm{p} K_{\mathrm{a}} 4$ the $k_{-1} / k_{2}$ ratio is $2 \times 10^{5}$ and $8 \times 10^{5}$,* respectively. In other words, the change from 3 to $\mathbf{1}$ favours $\mathrm{PhS}^{-}$expulsion for the basic amine, but it favours the amine leaving for a weakly basic amine.
